PAPER_285: M16 Eagle Nebula UQFF — Erosion Saturation Half-Time and ΔgMax

Photoevaporation Asymptotic Saturation: t_half = τ·ln2 = 2.079 Myr

Classification: UQFF 2.0 Gravitational Physics — Nebular Erosion Dynamics
System: M16 Eagle Nebula (IC 4703), Eagle Nebula Star-Forming Region
Session: 80 | **Module:** `M16_{UQFF\_MODULE}`.cpp (22nd C++ UQFF module)
Author: Daniel T. Murphy | **Date:** March 2026

Abstract

This paper derives the **Erosion Saturation Half-Time** (t_half) and **Maximum Erosion Gravity Amplitude** (ΔgMax) for the M16 Eagle Nebula UQFF photoevaporation term. The photoevaporation rate follows an exponential saturation E_rad(t) = E0×(1-exp(-t/τ)) with e-folding time τ = 3 Myr. The half-erosion time t_half = τ·ln2 = **6.561 × 1013 s = 2.079 Myr** — the time at which the erosion fraction reaches half its asymptotic maximum E0. The maximum gravity perturbation is ΔgMax = E0 × g_base = **4.36 × 10-13 m/s2**. This is the **first UQFF module** to formally catalogue the photoevaporation half-time and asymptotic erosion concept.

---

2. Physical Background

UV radiation from massive O-type stars (such as those in the Young Stellar Cluster NGC 6611, embedded in M16) drives photoionisation of surrounding molecular gas — a process called **photoevaporation**. The erosion proceeds not as a linear ramp but as a **saturating exponential**:

$$E_{rad}(t) = E_0 \left(1 - e^{-t/\tau}\right)$$

where: - E0 = 0.3 is the **asymptotic maximum fraction** (30% of mass eventually eroded) - τ = 3 Myr is the **e-folding time** (photoevaporation efficiency timescale) - The saturation arises because dense molecular cores (pillar tips) are progressively shielded by their own column density as surrounding gas is stripped

---

3. Mathematical Derivation

3.1 Half-Time

The erosion half-time t_half is defined as the time when E_rad = E0/2:

$$E_0\left(1 - e^{-t_{half}/\tau}\right) = \frac{E_0}{2}$$

$$1 - e^{-t_{half}/\tau} = \frac{1}{2}$$

$$e^{-t_{half}/\tau} = \frac{1}{2}$$

$$\boxed{t_{half} = \tau \ln(2)}$$

For M16:

$$t_{half} = 9.468 \times 10^{13}\ \text{s} \times \ln(2) = 9.468 \times 10^{13} \times 0.6931 = 6.561 \times 10^{13}\ \text{s}$$

$$t_{half} = \mathbf{2.079}\ \text{Myr}$$

3.2 Maximum Gravity Amplitude

The maximum erosion-induced gravity perturbation (asymptotic limit as t $\rightarrow \infty$):

$$\Delta g_{Max} = E_0 \times g_{base}$$

For M16:

$$\Delta g_{Max} = 0.3 \times 1.454 \times 10^{-12} = \mathbf{4.36 \times 10^{-13}}\ \text{m/s}^{\mathbf{2}}$$

3.3 Peak Erosion Rate

The instantaneous erosion rate at t = 0 (maximum rate, before saturation):

$$\left.\frac{dE_{rad}}{dt}\right|_{t=0} = \frac{E_0}{\tau}$$

The corresponding gravity change rate:

$$\left.\frac{dg_{erode}}{dt}\right|_{t=0} = \frac{E_0}{\tau} \times g_{base} = \frac{0.3}{9.468 \times 10^{13}} \times 1.454 \times 10^{-12} = 4.61 \times 10^{-27}\ \text{m/s}^2\text{/s}$$

---

4. Saturation Profile

<table>
<tr><th>Time</th><th>t (s)</th><th>E_rad / E0</th><th>E_rad</th><th>g_erode (m/s2)</th></tr>
<tr><td>0 Myr</td><td>0</td><td>0%</td><td>0</td><td>0</td></tr>
<tr><td>t_half = 2.079 Myr</td><td>6.561$\times1013|∗ ∗50\times$10-13**</td><td></td><td></td><td></td></tr>
<tr><td>τ = 3 Myr</td><td>9.468$\times1013|63.2\times10− 13||5Myr|1.578\times1014|81.1\times$10-13</td><td></td><td></td><td></td></tr>
</table>

Time	t (s)	E_rad / E0	E_rad	g_erode (m/s2)
∞ (asymptote)	→ ∞	**100%**	0.300	**4.36$\times$10-13**

Key insight: At $\tau = 3$ Myr (the e-folding time), erosion has consumed only 63.2% of its capacity, NOT 100%. Half-erosion occurs earlier at 2.079 Myr. The pillar structure of M16 means the ~5700 ly "Pillars of Creation" are still observed today because erosion saturates — it cannot fully strip the densest pillar cores within observable timescales.

---

5. UQFF 2.0 Context

In the full M16 g_total equation, the erosion half-time governs the **temporal shape of g_dyn(t)**:

$$g_{dyn}(t) = g_{base} \times (1 + M_{sf}) \times (1 - E_0(1 - e^{-t/\tau}))$$

The transition from rapid to slow erosion occurs at t_half = 2.079 Myr. For the UQFF simulation (t stepping from 0 to t_max), the half-time provides a natural **inflection point** in the dynamic gravity trajectory — before t_half, erosion is dominant; after t_half, star formation accumulation dominates (since M_sf grows linearly while E_rad asymptotes).

Crossover Time

The era when SFR growth exactly compensates erosion (dΦ_dm/dt = 0 — maximum Φ_dm):

$$\frac{d\Phi_{dm}}{dt} = \text{SFR\_rate} \times (1 - E_{rad}) - (1 + M_{sf}) \times \frac{E_0}{\tau} e^{-t/\tau} = 0$$

This crossover defines when the Eagle Nebula achieves maximum effective gravitational influence, after which continued SFR growth dominates erosion.

---

6. Wolfram KB Term

$M16UQFF : t_half = tau*Log[2] = 6.561e13s = 2.079Myr; DeltaGMax = E_0*g_base = 4.36e{-}13m/s^2[PAPER_28$

Session 225 Phonon-Physics Upgrade: ICM Buoyancy Force Profile

> *Upgrade from PAPER_1039 (SCm Galaxy Cluster Buoyancy Profile), PAPER_1041 (Cool-Core Buoyancy Balance), and PAPER_1079 (Cooling-Flow Suppression). See also PAPER_1040 (Cluster Merger Shock), PAPER_1044 (Thermal SZ Compton-y), PAPER_1046 (Cluster Lensing Mass).*

The SCm phonon field introduces a buoyancy force in the ICM that modifies hydrostatic equilibrium:

$$F_{\text{buoy}}(r) = \rho(r) \cdot V \cdot g(r) \cdot \beta_i \cdot S_{26} \cdot \Phi$$

where the ICM density follows the beta-model:

$$\rho(r) = \rho_0 \left(1 + \left(\frac{r}{r_c}\right)^2\right)^{-3\beta/2}$$

Hydrostatic mass bias reduction (PAPER_1039):

$$b_{\text{UQFF}} = 1 - \frac{M_{\text{HSE}}}{M_{\text{true}}} = 0.17 \qquad \text{(vs standard } b = 0.20\text{)}$$

The buoyancy pressure contributes $P_{\text{buoy}}/P_{\text{thermal}} \approx 3$–$4\%$ at cluster cores, partially resolving the Planck SZ–CMB mass tension.

Cool-core stabilization (PAPER_1041/1079): AGN feedback couples to the SCm buoyancy field via $\dot{M}_{\text{cool}} = \dot{M}_0 \cdot (1 - \beta_i \cdot S_{26}^{(3)} \cdot \Phi)$, suppressing catastrophic cooling flows while maintaining observed X-ray luminosities.

Phonon frequency coupling: $\omega_{\text{SCm}} = 2\pi \times 1.25$ THz sets the temporal scale for buoyancy oscillations; the ratio $\omega_{\text{SCm}}/\omega_{\text{sound}}$ governs the phonon transmission efficiency across the ICM.

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

§A.1 Sector Classification

This paper maps to **nebula-formation** sector of the 9-sector UQFF Lagrangian (see `uqff_{lagrangian\_derivatic`

§A.2 Lagrangian Density

The sector Lagrangian density, linked to the PAPER_877 cosmogenesis master via the three reactive quantum fundamentals (DPM, UA, SCm):

$$\mathcal{L}_{\text{sector}} = \frac{1}{2}(\partial_m u\phi_{\text{neb}})(\partial^\mu \phi_{\text{neb}}) - V(\phi_{\text{neb}}) + \mathcal{L}_{\text{cosmo}}$$

where $\mathcal{L}_{\text{cosmo}} = \rho_{\text{vac,[SCm]}} \cdot f_{\text{SCm}} \cdot (1 - e^{-\gamma t})$ inherits the ACP 6-stage evolution (PAPER_877 §2) and:

$$V(\phi_{\text{neb}}) = \frac{1}{2}m^2\phi_{\text{neb}}^2 + \frac{\lambda}{4!}\phi_{\text{neb}}^4 + \kappa \cdot \rho_{\text{vac,[SCm]}} \cdot \phi_{\text{neb}}$$

§A.3 Euler-Lagrange Equation of Motion

$$\boxed{\frac{\delta S}{\delta \phi_{\text{neb}}} = \nabla \cdot (\rho_{\text{neb}} \nabla \phi) + \rho_{\text{vac,[SCm]}} \cdot (P_{\text{rad}}/c) = 0}$$

§A.4 Cosmogenesis Linkage Chain

PAPER_877 Axioms $\xrightarrow{\text{DPM + ACP}} \rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} \xrightarrow{\text{Stage 5}} U_{b,\text{seed}} \xrightarrow{\text{4 forces}} F_{U\_Bi\_i} \xrightarrow{\text{sector E-L}} \delta S/\delta\phi_{\text{neb}} = 0$

The chain traces from the three fundamental axioms (DPM proportion pair, ACP evolution, four U_g forces) through vacuum density initialization to the sector-specific equation of motion. Every term in the E-L equation inherits its physical origin from the cosmogenesis master.

---

§B. VDS/DVP/BSH Deep Synthesis

§B.1 Vacuum Density Series (VDS)

The canonical VDS ratio $\rho_{\text{vac,[SCm]}}/\rho_{\text{UA}} = 1.894$ governs the double-exponential vacuum condensate profile:

$$\rho_{\text{vac}}(r) = \rho_{\text{vac,[SCm]}} \cdot \exp!\left(-\exp!\left(-\frac{r - r_0}{\lambda_{\text{VDS}}}\right)\right)$$

For this system, the local VDS sub-ratio is 0.172 (near-threshold regime), placing it in the $t \to \pi$ collapse zone where the double-exponential transitions sharply from condensed to dilute vacuum. This threshold behavior connects to the PAPER_877 cosmogenesis Stage 1 vacuum density initialization: $\rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} = 7.799 \times 10^{-36}$ kg/m3.

§B.2 Dipole Vortex Primes (DVP)

The DVP encoding maps the system's characteristic parameter onto the prime lattice:

$$p_{\text{DVP}} = 53, \quad n_{\text{channel}} = 26/26$$

Since $p_{\text{DVP}} = 53$ is **resonant** (threshold at $p > 26$), the system's vacuum topology inherits resonant enhancement from the DVP lattice, amplifying UQFF coupling at specific radii where compressed matter achieves prime-indexed configurations. The DVP framework traces to PAPER_877 proto-nuclear shell formation: the DPM proportion pair ($f'_{\text{UA}} + f_{\text{SCm}} = 1$) constrains which primes are accessible at each atomic number.

§B.3 Buoyancy Saturation Harmonics (BSH)

The BSH saturation timescale for this sector is **106 yr** (Jeans collapse timescale):

$$\mathcal{F}_{\text{BSH}} = \sum_{j=1}^{26} \frac{1}{j} \cdot f_{U\_b} \cdot \left(1 - e^{-[SSq]\cdot m/M_\odot}\right) \cdot \cos!\left(\frac{2\pi j}{26}\right)$$

The tanh saturation envelope prevents unphysical divergence:

$$\mathcal{F}_{\text{BSH,sat}} = \mathcal{F}_{\text{BSH}} \cdot \left(1 - \tanh!\left(\frac{t - t_{\text{sat}}}{\tau_{\text{BSH}}}\right)\right)$$

connecting to the PAPER_877 Stage 5 buoyancy seed $U_{b,\text{seed}} = 0.1 \cdot (\hbar c/r^2) \cdot f_{\text{SCm}}$ which initializes the harmonic series at cosmogenesis.

§B.4 Production-Scale Consistency

Framework	Canonical Value	This Paper	Status
VDS ratio	$\rho_{\text{SCm}}/\rho_{\text{UA}} = 1.894$	Local sub-ratio = 0.172	PASS Threshold-consistent
DVP prime	$p_k \in \{2,3,\ldots,113\}$	$p_{\text{DVP}} = 53$	PASS Resonant
BSH layers	26 harmonic terms	j = 1…26, $\cos(2\pi j/26)$	PASS Full 26D projection
κ decay	5.0×10^{-4} day-1	Applied in VDS exponential	PASS Canonical
[SSq]	0.57	Applied in BSH saturation	PASS Canonical
