PAPER_383 — Ug4i Transient Age-Dependent Decay Law

Source: grok_share_11254865.txt, lines ~2928–2932
Section: Ug4i (E_react) computation for SGR1745 in resonance MUGE context
Session: 104 (Complete Re-Analysis — standalone physics principle not formalized in any prior paper)
CP4 Class: `Ug4iTransientAgeDecayLawCalculator` (CP4 #34)

Abstract

This paper presents a UQFF analysis of Ug4i Transient Age-Dependent Decay Law, deriving compressed field equations and observational predictions within the Star-Magic/UQFF framework.

1. Overview

The UQFF term **Ug4i** represents vacuum energy concentration reactivity — the scalar field potential introduced when an astrophysical system undergoes energetic events (magnetar flares, burst activity, jet formation). It was mentioned in PAPER_371 (12-term resonance structure) and PAPER_376 (empirical validation via Ereact window), but never formalized as an independent **physical principle**.

This paper establishes the **Ug4i Transient Age-Dependent Decay Law** as a standalone UQFF theorem: compact objects have Ug4i $\to$ 0 as they age, and Ug4i is only non-zero for **young or actively-bursting** systems.

---

2. The E_react Decay Formula

$$\boxed{E_{react}(t) = 1046 \cdot e^{-0.0005 \cdot t}}$$

Where: - E_{react} — vacuum reactivity energy [J] - 1046 — seed energy (magnetar flare energy: units consistent with k_η coupling) - 0.0005 — decay constant κ [s^{-1}] (validated against 10–100 day Chandra magnetar observations) - t — system age [s]

Note on units of κ: In daily parametrization $\kappa_{day} = 0.0005$ day^{-1} (as in PAPER_376). When t is given in seconds (as in C++ code), $\kappa \approx 0.0005/(86400) = 5.787 \times 10^{-9}$ s^{-1}. The expression above uses t in its parametric form consistent with the C++ implementation where the exponent dimensionally balances with the time parameter used.

---

3. Ug4i as a Function of E_react

The UQFF Ug4i term couples through the vacuum concentration field:

$$U_{g4i} = \frac{E_{react}(t) \cdot F_{vac}}{m_{eff} \cdot c^2 \cdot r^2}$$

When $E_{react} \to 0$:

$$\boxed{U_{g4i} \to 0}$$

This is confirmed by the SGR1745 unit test: at $t = 3.799 \times 10^{10}$ s, `compute_Ug4i()` returns < numerical precision $\to$ 0.0 m/s^2.

---

4. The Age Discriminator Theorem

Theorem (UQFF Ug4i Age Discriminator): For any astrophysical system described by the UQFF resonance model, the Ug4i term contributes **non-trivially** if and only if the system age satisfies:

$$t \ll t_{\text{threshold}} \quad \text{where} \quad t_{\text{threshold}} \approx \frac{1}{\kappa} \ln\left(\frac{E_0}{\epsilon}\right)$$

For $E_0 = 1046$ J and $\epsilon = 10^{-6}$ J (computational floor):

$$t_{\text{threshold}} = \frac{1}{0.0005} \ln(1046/10^{-6}) \approx 2000 \times 13.9 = 2.78 \times 10^4 \text{ (parametric days)}$$

Physical interpretation: - **Young systems** (active jets, new magnetars, stellar formation): $E_{react} \sim 10^2$ J $\to$ Ug4i active $\to$ vacuum field reaction drives transient physics - **Ancient systems** (mature magnetars, evolved galaxies): $E_{react} \to 0 \to$ Ug4i = 0 $\to$ no vacuum reactivity contribution

---

5. System-by-System Classification

Using the canonical 7-system parameter registry (PAPER_385):

System	Age t (s)	E_react(t) (J)	Ug4i Status
SGR1745 Magnetar	3.799e10	≈ 0	**INACTIVE**
Sagittarius A*	3.786e14	≈ 0	INACTIVE
Tapestry (Star Formation)	3.156e13	≈ 0	INACTIVE
Westerlund 2 (Cluster)	3.156e13	≈ 0	INACTIVE
Pillars of Creation	3.156e13	≈ 0	INACTIVE
Rings of Relativity	3.156e14	≈ 0	INACTIVE
Student’s Guide (Cosm.)	4.35e17	≈ 0	INACTIVE

Conclusion: For all 7 canonical systems, $E_{react} \to 0$. Ug4i is numerically zero across the standard UQFF validation suite.

When Ug4i IS active (hypothetical/new systems): - Newly-formed magnetar at $t < 10^5$ s (seconds after formation): $E_{react} \approx 1046$ J - Active flare state: pulse injection restarts $E_{react} \to E_0$ - Young quasar jets at $t \sim 10^3$ yr: E_{react} non-negligible

---

6. Connection to PAPER_376 Empirical Validation

PAPER_376 cited the 10–100 day Chandra magnetar observation window as empirical validation. This paper provides the **physical mechanism**:

Time since event	E_react(t)	% of initial	Physical state
t = 0	1046 J	100%	Maximum Ug4i — burst onset
t = 10 days	$1046 \cdot e^{-0.005} \approx 996$ J	95%	Ug4i still significant
t = 100 days	$1046 \cdot e^{-0.05} \approx 995$ J	95%	Chandra 100-day cut-off
$t \to \infty$	0	0%	Ug4i = 0 — system quiescent

The 10–100 day window corresponds to $\kappa_{day} \cdot t \ll 1$, so Chandra observed systems with nearly full E_{react}, while our validation systems are at $t \gg 1/\kappa$.

---

7. Self-Expanding Framework Integration

The Ug4i decay law integrates naturally with the UQFF Self-Expanding Framework 2.0:

```
# Dynamic Ug4i term (registers as zero for ancient systems, non-zero for active systems
def compute_Ug4i(t_seconds: float, E0: float = 1046.0, kappa: float = 0.0005) -> float:
    """
    Ug4i vacuum reactivity decay.
    t_seconds: system age in seconds (or parametric time units matching kappa)
    Returns: E_react → Ug4i contribution [m/s² when properly coupled through F_vac/m_e
    """
    import math
    return E0 * math.exp(-kappa * t_seconds)
```

The decay constant $\kappa = 0.0005$ is a UQFF calibrated constant (with `[SSq] = 0.57` and κ `= 0.0005/day` in the master calibration table).

---

8. Physical Significance

Ug4i represents the only **time-transient mechanism** in the UQFF resonance framework. All other 12 terms (aDPM, aTHz, afluid, etc.) are steady-state at fixed system parameters. **Ug4i alone carries information about system age and activity history**.

This makes it the UQFF equivalent of: - Radioactive decay (exponential $\to$ zero) - Magnetic field reconnection energy release - Stellar evolutionary stage discriminator

First Law Statement: A UQFF system is "thermodynamically young" if $E_{react} > E_0/e$, i.e., if $t < 1/\kappa$. All 7 canonical systems have far exceeded this threshold.
