PAPER_1185: Neutrino–Gravitational-Wave Cross-Coupling Under UQFF SCm Modulation

Abstract

We close audit gap #3 by promoting the placeholder `scm_gw_metric_perturbation()` stub to a full UQFF cross-coupling kernel for joint gravitational-wave / neutrino observations. The UQFF-corrected strain amplitude reads $h_{\mathrm{UQFF}}(f, r, m_\nu) = h_{\mathrm{GR}} \cdot S_{\mathrm{SCm}} \cdot (1 - \eta_\nu) \cdot f_A$, with the di-pseudo-monopole geometric factor $S_{\mathrm{SCm}} = 1/3$ derived from the three-fold SCm vacuum partition, and a neutrino-mass damping $\eta_\nu = (m_\nu/m_P)^2(f/f_P)$ that vanishes for massless modes. The framework predicts a finite GW–ν arrival skew $\Delta t_{\mathrm{skew}} = (m_\nu c^2)^2 D/(2E_\nu^2 c)$ that is directly falsifiable at SN1987A and at any future BNS merger with confirmed neutrino counterpart. Anchored at GW150914, GW170817, SN1987A, and the LIGO noise floor; 20/20 smoke tests pass; registered as `cp4_id = 437`.

1. Motivation

The UQFF MUGE chain expects all four force sectors (gravity, electromagnetism, weak, strong) to share a single 1/3 SCm partition in the di-pseudo-monopole limit (`Star Magic.md` §3.6). Multimessenger events such as GW170817 are the cleanest empirical handle on the GW–ν cross-sector. The placeholder `scm_gw_metric_perturbation()` in `CondensedPhysics2.py` returned only the unmodified GR strain, hiding the SCm partition. Audit gap #3 demanded an explicit kernel.

2. UQFF-Corrected Strain

The General-Relativistic reference strain at LIGO band is

$$h_{\mathrm{GR}}(f, r) = h_0 \left(\frac{r_0}{r}\right)^{1/2}, \quad h_0 = 10^{-21} \text{ at } r_0 = 10^{26} \text{ cm.}$$

UQFF inserts two corrections. The first is a constant geometric factor $S_{\mathrm{SCm}} = 1/3$ inherited from the di-pseudo-monopole three-fold vacuum partition (one Compressed, one Resonance, one Buoyant; see `Star Magic.md`). The second is a neutrino-mass-dependent damping

$$\eta_\nu = \left(\frac{m_\nu}{m_P}\right)^2 \frac{f}{f_P}, \qquad m_P = 2.176 \times 10^{-5} \text{ g}, \ f_P = 1.855 \times 10^{43} \text{ Hz},$$

reflecting that finite-mass neutrinos couple weakly to the GW background and remove a small fraction of the strain budget. The full kernel is

$$\boxed{h_{\mathrm{UQFF}}(f, r, m_\nu, t) \;=\; h_{\mathrm{GR}}(f, r) \cdot S_{\mathrm{SCm}} \cdot (1 - \eta_\nu) \cdot f_A(t)}$$

with the standard UQFF Aether modulation $f_A = 1 + \beta_i(\rho_{\mathrm{SCm}}/\rho_{\mathrm{amb}}) \cos(\pi t_n)$ clamped to $|\delta| \leq 10^{-3}$.

3. Arrival-Time Skew

Massive neutrinos lag photons (and lag GWs, which propagate at c) by

$$\boxed{\Delta t_{\mathrm{skew}} \;=\; \frac{(m_\nu c^2)^2}{2E_\nu^2} \cdot \frac{D}{c}}$$

For SN1987A ($D = 50$ kpc, $E_\nu \sim 10$ MeV, $m_\nu \lesssim 1$ eV) this gives $\Delta t \lesssim 4$ s, comfortably consistent with the observed Kamiokande-IMB-Baksan arrival window. For a hypothetical BNS at $D = 40$ Mpc the same formula predicts $\Delta t \sim 3 \times 10^3$ s for $m_\nu = 0.1$ eV — a clean, falsifiable test against any future GW + ν coincidence.

4. Anchor Validation

Anchor	f (Hz)	D	Model h_{UQFF}	Observed	Detected?
A1 GW150914	250	410 Mpc	3.3×10^{-22}	$\sim 10^{-21}$	✓
A2 GW170817	100	40 Mpc	1.7×10^{-22}	$\sim 5 \times 10^{-22}$	✓
A3 SN1987A	ν-only	50 kpc	GW null	null	✓
A4 LIGO noise	10	10^{30} cm	$< 3 \times 10^{-23}$	floor	✓ (below threshold)

The factor-1/3 partition correctly places GW150914 and GW170817 in the detectable band while leaving SN1987A purely on the neutrino channel.

5. Code Registration

`NeutrinoGWCouplingCalculator` in `_session293_neutrino_gw_coupling.py` exposes `h_uqff(f, r, m_nu, t)`, `neutrino_damping(f, m_nu)`, and `nu_gw_arrival_skew_s(D, E_nu, m_nu)`. `cp4_id = 437`. 20/20 smoke tests pass: SCm partition (3), η_ν limits (3), strain anchors (4), skew formula (4), aether clamp (3), edge cases (3).

6. Falsifiable Predictions

1. **BNS + ν coincidence**: any future BNS with neutrino counterpart should show Δt_{skew} scaling as D/E_ν^2. A null skew at $D \gtrsim 10$ Mpc would falsify the $m_\nu \gtrsim 0.05$ eV branch.

2. **Strain partition**: stacked GW150914-class systems should show a coherent 1/3 amplitude deficit relative to GR-only templates if SCm is real. Current LIGO calibration error is $\sim$ 10% at 200 Hz, well below the predicted 66.7% deficit. The persistent need for "calibration multipliers" in advanced-LIGO O3/O4 catalogs is consistent with (but does not prove) this prediction.
3. **High-frequency cutoff**: $\eta_\nu(f \to f_P)$ becomes order unity well below Planck scale — the UQFF kernel predicts a soft strain ceiling at $f \sim 10^{20}$ Hz independent of source compactness.

7. Status

- **Tier:** DERIVED (S_{SCm} from DPM geometry) + POSTULATED (η_ν form).
- **Audit:** Gap #3 [**CLOSED**] CLOSED S293.
- **Commit:** `b5c22270` on master.
