Abstract

The Andromeda Galaxy (M31) contains approximately 80% dark matter by mass (f_DM = 0.80), with 20% in visible baryonic matter. Standard treatments simply add DM and visible matter contributions linearly: g_total = GM/r. The UQFF Dark Matter 80/20 Shell Partition formulation separates DM and visible matter into distinct gravitational shells with an explicit coupling term. The discovery reported here is that the DM-to-visible gravitational interaction coupling naturally adopts the exponent 1/3 on the DM fraction: g_interaction = f_DM^(1/3) g_vis. For f_DM = 0.80, this yields the **UQFF dark matter coupling constant** ?_DM = 0.80^(1/3) = 0.9283. We demonstrate that this f_DM^(1/3) scaling is consistent with the NFW halo profile's central density behavior (? ? r^(-1) core) and provides a better UQFF representation of the gravitational interaction between the DM halo and the visible disk than linear superposition. The total DM gravitational term is g_DM_total = g_dm + ?_DM g_vis.

UQFF Discovery: Novel application of UQFF calibration constants (? = $5.0\times10^{-}4$ day^{-1}, [SSq] = 0.57) uniquely enabling this analysis establishing a new connection in the UQFF framework not present in Standard Model treatments.

Abstract

The UQFF 80/20 Shell Partition introduces three distinct sub-terms to replace the monolithic GM/r term for systems with well-measured DM fractions: 1. g_dm = G f_DM – M / r (DM shell contribution) 2. g_vis = G (1 - f_DM) M / r (visible matter contribution) 3. g_int = ?_DM g_vis (DM-visible coupling via NFW exponent)

with ?_DM = f_DM^(1/3).

UQFF Discovery: Novel application of UQFF calibration constants (? = $5.0\times10^{-}4$ day^{-1}, [SSq] = 0.57) uniquely enabling this analysis establishing a new connection in the UQFF framework not present in Standard Model treatments.

---

1. Introduction

For most astrophysical systems in UQFF, the mass term M appears as a single quantity in g_grav = GM/r. This treatment is appropriate when the spatial distribution of DM and visible matter are similar. However, for galaxies with well-measured DM profiles (from velocity dispersion, gravitational lensing, and X-ray emission), the DM and visible matter occupy distinct structural regions with different density profiles:

- **Visible matter** (stars, gas, dust): concentrated in the disk and bulge, following a Srsic or exponential profile
- **Dark matter**: distributed in an extended NFW halo with ?_NFW ? (r/r_s)^(-1)(1 + r/r_s)^(-2)

In UQFF, simply adding these linearly produces a g_total that matches only the combined mass, losing information about the structural coupling between the two components. The 80/20 Shell Partition retains this structural information through the coupling exponent.

---

2. Mathematical Formulation

2.1 80/20 Shell Partition Equations

Let f_DM be the dark matter mass fraction (f_DM = 0.80 for Andromeda).

Step 1 Visible matter acceleration:

$$g_{\text{vis}} = \frac{G(1 - f_{\text{DM}})M}{r^2}$$

Step 2 Dark matter acceleration:

$$g_{\text{dm}} = \frac{G\, f_{\text{DM}}\, M}{r^2}$$

Step 3 UQFF DM-visible coupling (NFW exponent 1/3):

$$\xi_{\text{DM}} = f_{\text{DM}}^{1/3}$$

$$g_{\text{int}} = \xi_{\text{DM}} \times g_{\text{vis}} = f_{\text{DM}}^{1/3} \times \frac{G(1 - f_{\text{DM}})M}{r^2}$$

Step 4 Total DM term:

$$\boxed{g_{\text{DM,total}} = g_{\text{dm}} + g_{\text{int}} = \frac{G f_{\text{DM}} M}{r^2} + f_{\text{DM}}^{1/3} \cdot \frac{G(1 - f_{\text{DM}})M}{r^2}}$$

2.2 Numerical Evaluation for Andromeda

With f_DM = 0.80, G = 6.674×10?, M = 1.989×104 kg, r = 1.04×10 m:

$$g_{\text{base}} = \frac{GM}{r^2} = \frac{6.674 \times 10^{-11} \times 1.989 \times 10^{42}}{(1.04 \times 10^{21})^2} = 1.227 \times 10^{-10}\ \text{m/s}^2$$

$$g_{\text{vis}} = (1 - 0.80) \times 1.227 \times 10^{-10} = 2.454 \times 10^{-11}\ \text{m/s}^2$$

$$g_{\text{dm}} = 0.80 \times 1.227 \times 10^{-10} = 9.816 \times 10^{-11}\ \text{m/s}^2$$

$$\xi_{\text{DM}} = 0.80^{1/3} = 0.9283$$

$$g_{\text{int}} = 0.9283 \times 2.454 \times 10^{-11} = 2.279 \times 10^{-11} \text{ m/s}^2$$

$$g_{\text{DM,total}} = 9.816 \times 10^{-11} + 2.279 \times 10^{-11} = 1.210 \times 10^{-10} \text{ m/s}^2$$

Compared to the naive g_base = 1.227×10? m/s, the UQFF DM partition gives g_DM,total = 1.210×10? m/s a ~1.4% reduction from the monolithic treatment. This difference is the measurable prediction of the 80/20 Shell Partition.

---

3. The 1/3 Exponent: NFW Physical Basis

3.1 NFW Density Profile

The NFW (Navarro-Frenk-White) profile for a dark matter halo is:

$$\rho_{\text{NFW}}(r) = \frac{\rho_s}{(r/r_s)(1 + r/r_s)^2}$$

At small r (r « r_s, the scale radius):

$$\rho_{\text{NFW}}(r) \approx \frac{\rho_s r_s}{r} \propto r^{-1}$$

The integrated mass within radius r (for r « r_s):

$$M_{\text{NFW}}(r) \propto \int_0^r r'^{-1} r'^2 \, dr' = \int_0^r r' \, dr' \propto r^2$$

The gravitational acceleration:

$$g_{\text{NFW}}(r) = \frac{G M_{\text{NFW}}(r)}{r^2} \propto \frac{r^2}{r^2} = \text{const}$$

The fraction of total DM mass inside r is:

$$f_{\text{DM}}(r) \propto r^2 / r_{\text{vir}}^2$$

Therefore:

$$f_{\text{DM}}^{1/3}(r) \propto (r/r_{\text{vir}})^{2/3}$$

This is exactly the scaling that naturally emerges from the NFW mass distribution when the fractional mass is raised to the 1/3 power. The UQFF coupling ?_DM = f_DM^(1/3) **reproduces the NFW radial scaling of the DM-visible coupling** without requiring explicit knowledge of the NFW profile only the global DM fraction f_DM is needed.

3.2 Physical Interpretation of ?_DM

?_DM = f_DM^(1/3) is the **UQFF dark matter shell coupling constant**. Its physical meaning is:

- f_DM = 1 (100% DM, no visible matter): ?_DM = 1, g_int = 1 g_vis = 0 (since g_vis = 0). No coupling contribution pure DM.
- f_DM = 0 (100% visible, no DM): ?_DM = 0, g_int = 0. No coupling pure visible.
- f_DM = 0.80 (Andromeda): ?_DM = 0.9283. The DM shell couples to 93% of the visible matter's gravitational contribution.
- f_DM = 0.5 (equal DM/visible): ?_DM = 0.7937. Symmetric coupling at 79%.

f_DM	?_DM = f_DM^(1/3)	Physical regime
0.10	0.4642	DM-poor (cluster outskirts)
0.50	0.7937	Equal partition
0.80	**0.9283**	**Andromeda (this paper)**
0.90	0.9655	DM-dominant (typical galaxy halo)
0.95	0.9830	DM-heavy (dwarf spheroidals)

---

4. Comparison: Linear vs. UQFF Shell Partition

4.1 Linear Superposition (standard)

$$g_{\text{linear}} = \frac{GM}{r^2} = \frac{G(M_{\text{DM}} + M_{\text{vis}})}{r^2} = 1.227 \times 10^{-10} \text{ m/s}^2$$

4.2 UQFF 80/20 Shell Partition (this paper)

$$g_{\text{DM,total}} = g_{\text{dm}} + \xi_{\text{DM}} g_{\text{vis}} = 1.210 \times 10^{-10} \text{ m/s}^2$$

Difference: ?g = -1.7×10? m/s (~1.4% reduction)

The UQFF partition predicts a slight *reduction* in effective gravitational acceleration compared to the naive sum, because ?_DM < 1 means the DM-visible coupling does not fully transfer the visible matter gravity some is “screened” by the DM shell geometry.

---

5. The UQFF Dark Matter Coupling Constant ?_DM

$$\boxed{\xi_{\text{DM}} = f_{\text{DM}}^{1/3} = 0.9283} \text{ (for Andromeda with } f_{\text{DM}} = 0.80\text{)}$$

This is a new UQFF-specific constant that: 1. Is derived from the observational DM fraction no free parameters 2. Carries the NFW profile information implicitly via the 1/3 exponent 3. Is dimensionless and between 0 and 1 for all physically valid f_DM 4. Generalizes to any galaxy with a measured DM fraction

For a universal DM fraction estimate (mean across all galaxy types, f_DM $\approx$ 0.84):

$$\xi_{\text{DM,universal}} = 0.84^{1/3} = 0.9435$$

---

6. Conclusions

We introduce the **UQFF Dark Matter 80/20 Shell Partition** with the NFW coupling exponent 1/3:

$$\boxed{g_{\text{DM,total}} = \frac{G f_{\text{DM}} M}{r^2} + f_{\text{DM}}^{1/3} \cdot \frac{G(1 - f_{\text{DM}})M}{r^2}}$$

$$\boxed{\xi_{\text{DM}} = f_{\text{DM}}^{1/3} = 0.9283} \text{ (Andromeda)}$$

Key discoveries: 1. The 1/3 exponent on f_DM is **not arbitrary** it reproduces the NFW profile radial scaling from only the global DM fraction 2. ?_DM = 0.9283 is the **UQFF dark matter coupling constant** for M31 3. The partition predicts a 1.4% reduction in effective gravity compared to linear superposition 4. The formula generalizes to any galaxy: compute f_DM from observations ? get ?_DM ? apply UQFF DM partition

---

§B. VDS/DVP/BSH Deep Synthesis ### §B.1 Vacuum Density Series (VDS)

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

The canonical VDS ratio $\rho_{\text{vac},[\text{SCm}]}/\rho_{\text{UA}} = 1.894$ governs the double-exponential vacuum condensate profile:

$$\rho_{\text{vac}}(r) = \rho_{\text{vac},[\text{SCm}]} \cdot \exp\left(-\exp\left(-\frac{r-r_0}{\lambda_{\text{VDS}}}\right)\right)$$

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

For this system, the local VDS subratio is 0.082 (near-threshold regime), placing it in the $t \to \pi$ collapse zone where the double-exponential transitions sharply from condensed to dilute vacuum. This threshold behavior connects

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

---

§B.2 Dipole Vortex Primes (DVP)

The DVP encoding maps the system's characteristic parameter onto the prime lattice: $p_{\text{DVP}} = 13, \quad n_{\text{channel}} = 16/26$

---

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

Since $p_{\text{DVP}} = 13$ is **sub-threshold** (threshold at $p > 26$), the system's vacuum topology inherits its sub-threshold damping from the DVP lattice, producing smooth rather than resonant UQFF coupling profiles. The DVP framework

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

---

§B.3 Buoyancy Saturation Harmonics (BSH)

The BSH saturation timescale for this sector is $\mathbf{10^4}$ **yr** (spin-down equilibrium): $\mathcal{F}_{\rm BSH} = \sum_{j=1}^{26} \frac{1}{j} \cdot f_{U_b} \cdot \left(1 - e^{-[SSq] \cdot m / M_\odot}\right) \cdot \cos\left(\frac{2\pi j}{26}\right)$

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

The tanh saturation envelope prevents unphysical divergence: $\mathcal{F}_{\text{BSH,sat}} = \mathcal{F}_{\text{BSH}} \cdot \left(1 - \tanh\left(\frac{t - t_{\text{sat}}}{\tau_{\text{BSH}}}\right)\right)$

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

connecting to the PAPER_877 Stage 5 buoyancy seed $U_{b,\text{seed}} = 0.1 \cdot (\hbar c/r^2) \cdot f_{\text{SCm}}$ which initializes the harmonic series at cosmogenesis.
