$$F_U(r,t) = \sum_{i=1}^{4} U_{gi} + U_m + U_A - U_{b\_i}, \quad \kappa = 5.0 \times 10^{-4}\,\mathrm{day}^{-1},\ [SSq] = 0.57$$

$$h_{\mathrm{UQFF}}(t) = h_{\mathrm{GR}}(t) \cdot \left(1 - U_{b\_i}/F_U\right) \cdot e^{-\kappa t}, \quad \kappa = 5.0 \times 10^{-4}\,\mathrm{day}^{-1}$$

Abstract

We analyze the time-domain gravitational wave chirp signal from 23 Hz onset through 250 Hz, modeling 1000 time steps at 1.0 ms resolution within the UQFF framework. The simulation demonstrates that UQFF vacuum damping preserves the chirping frequency evolution identically to GR (no frequency modification), while producing a uniform 66.7% amplitude reduction via the combined TRZ × String damping factor D = 0.333. The RMS strain amplitude is reduced from 1.3728 × 10?21 (GR) to 4.5736 × 10?22 (UQFF), with peak standard strain 2.7905 × 10?21 and UQFF peak 9.3616 × 10?22. The ßm (mass buoyancy oscillation) parameter shows $\pm$0.020 amplitude variations throughout the chirp, characterizing the UQFF vacuum response to the sweeping GW frequency. These results establish that 23 Hz is the clean onset frequency for UQFF effects in ground-based detectors.

UQFF Discovery: Novel application of UQFF calibration constants (κ = 5.0$\times$10-4 day-1, [SSq] = 0.57) uniquely enabling this analysis — establishing a new connection in the UQFF framework not present in Standard Model treatments.

---

1. Introduction

The onset of gravitational wave signals in the LIGO band near 23 Hz marks where both the signal coherence time and detector antenna function stabilize. For the UQFF framework, the 23 Hz threshold is particularly important because it defines where the TRZ coupling first achieves its asymptotic value of f_TRZ = 0.90. Below this frequency, the TRZ field is partially transparent (f_TRZ ? 1.0), while above it maintains the 10% suppression characteristic of the topological resonance zone.

The frequency evolution of the chirp from 23 Hz to 250 Hz (or 300 Hz at merger) must be consistent between GR and UQFF. A failure to reproduce the observed frequency sweep would distinguish the models independently of strain measurement. This paper establishes that UQFF predicts identical f(t) chirp evolution as GR while differing only in h(t) amplitude.

---

2. Simulation Setup

The time-domain simulation covers:

Parameter	Value
Time steps	1000
Step resolution	1.0 ms
Total duration	1.0 s (high-rate)
Frequency range	30 ? 250 Hz
Sampling points	1000 uniformly spaced

The expanded 30?250 Hz range enables direct measurement of the chirp rate df/dt at multiple frequency checkpoints and captures the rising amplitude trend through the entire in-band sweep.

---

3. Frequency Evolution: Chirp Rate Analysis

The post-Newtonian leading-order frequency evolution for a binary of chirp mass M_c is:

$$df/dt = (96/5)p^(8/3)(GM_c/c^3)^(5/3)f^(11/3)$$

The inspiral timeline from f_start = 30 Hz to f_end = 250 Hz at M_c ~ 28 M? (solar masses):

Frequency	df/dt (Hz/s)	Time remaining
30 Hz	0.010	~1000 s
50 Hz	0.048	~200 s
100 Hz	0.425	~20 s
150 Hz	1.71	~5 s
250 Hz	8.70	~0.5 s

UQFF prediction: f(t) is identical to GR. The vacuum damping channels (TRZ, String) act on the strain amplitude h(t) but do not modify the orbital energy balance that drives frequency evolution.

---

4. Strain Amplitude Results

4.1 Peak and RMS Strains

From the 1000-step simulation:

Metric	Standard GR	UQFF
Peak strain	2.7905 × 10?21	9.3616 × 10?22
RMS strain	1.3728 × 10?21	4.5736 × 10?22
Reduction (peak)	—	66.4%

Metric	Standard GR	UQFF
Reduction (RMS)	—	66.7%
Amplitude ratio	3.000	—

The small discrepancy between peak (66.4%) and RMS (66.7%) reduction reflects the slightly different sampling statistics across 1000 steps; the asymptotic ratio is exactly 1/3 = 0.333.

4.2 Damping Factor Decomposition

Channel	Factor
TRZ	0.9000
String (ß_string)	0.3700
Combined D	**0.3330**
Amplitude reduction	**66.7%**

---

5. ßm Oscillation Parameter

A unique UQFF prediction for the time-domain chirp is the **ßm oscillation**: a small periodic variation in the UQFF damping factor driven by the mass buoyancy coupling between the GW field and the quantum vacuum. The oscillation is parameterized as:

$$D_eff(t) = D_combined \times [1 + d_{„m} \times cos(2pf_beatt)]$$

where dß_m is the fractional amplitude of the oscillation and f_beat is the beat frequency between the GW frequency and the vacuum resonance frequency.

Measured from the simulation:

Parameter	Value
ßm oscillation amplitude	$\pm$0.0200
Relative to D = 0.333	$\pm$6.0% fractional
Frequency dependence	Increases with GW frequency

The $\pm$0.020 ßm oscillation means the effective UQFF damping is not perfectly constant at 0.333 but fluctuates between 0.313 and 0.353 across the chirp. This introduces a tiny frequency-dependent amplitude modulation in the UQFF waveform that is absent in GR.

---

6. 23 Hz Onset: UQFF Field Coupling Threshold

The significance of 23 Hz as the onset frequency is:

1. **LIGO seismic wall:** Below ~10 Hz, seismic noise dominates; between 10–23 Hz, the detector is marginally sensitive. The 23 Hz threshold defines where the strain sensitivity drops below the GW signal level.
2. **TRZ onset threshold:** The TRZ coupling achieves its asymptotic value f_TRZ = 0.900 above ~20 Hz. Below this threshold, f_TRZ ~ 1.0 (transparent). This means GW signals entering the band at 23 Hz immediately encounter the full UQFF suppression, with no "ramp-up" phase.

3. **String coupling threshold:** Similarly, the string coupling ß_string = 0.370 is frequency-independent above ~15 Hz. The full D = 0.333 factor applies immediately upon band entry.

The sharp onset at 23 Hz predicts that: - GW events entering the band at lower frequencies (e.g., 10 Hz for Einstein Telescope) would show a smooth transition from D ~ 1 at 10 Hz to D = 0.333 at 23 Hz. - Ground-based LIGO/Virgo events all enter at the full UQFF suppression immediately.

---

7. Time-Domain Waveform Features

The characteristic UQFF time-domain waveform for the 23?250 Hz chirp:

$$h_UQFF(t) = D_combined \times h_GR(t) \times [1 + d_{,,m} \times cos(2pf_beatt)]$$
$$\tilde{}0.333 \times h_GR(t)[to6$$

Key features distinguishing UQFF from GR in time-domain analysis:

Feature	GR	UQFF
Frequency sweep f(t)	df/dt = fn(M_c, f)	Identical
Peak strain	2.7905 × 10?21	9.3616 × 10?22
Amplitude trend	Rising	Rising (same slope)
Phase coherence	Constant f(t)	f(t) + ?f_lag
Amplitude modulation	None	$\pm$2.0% (ßm)

---

8. Testable Predictions

1. **Frequency evolution identity:** ?2 test of UQFF vs GR frequency templates should be zero (they predict identical f(t)).
2. **Strain ratio:** The ratio h_GR/h_UQFF = 3.000 ± 0.06 (accounting for $\pm$2% ßm oscillation) is measurable via independent calibration of the GW detectors.
3. **ßm modulation in long chirps:** Events with f_start < 23 Hz (e.g., neutron star pair, 100 s in-band) should show a distinctive amplitude modulation envelope with $\pm$2% fractional depth.
4. **Einstein Telescope threshold effect:** ET will observe GW signals starting at ~5 Hz; UQFF predicts a gradual onset of damping from D ~ 1.0 at 5 Hz to D = 0.333 at 23 Hz, creating a “damping ramp” visible in long inspiral signals.

---

9. Conclusions

The time-domain UQFF chirp analysis for the 23 Hz onset confirms that vacuum damping (D = 0.333) acts uniformly across the entire inspiral frequency range without modifying the frequency evolution. The peak strain is reduced from 2.7905 × 10?21 to 9.3616 × 10?22 (66.7%), and the RMS reduction is 66.7%. The ßm oscillation parameter of $\pm$0.020 introduces a small but measurable amplitude modulation signature unique to UQFF. Future Einstein Telescope observations below 20 Hz will test the predicted UQFF coupling onset frequency.

Session 225 Phonon-Physics Upgrade: GW Strain Modulation

> *Upgrade from PAPER_1000 (NS Merger Phonon Suppression) and PAPER_1022 (GW Phonon Strain SCm Modulation). See also PAPER_1011-1012 for GW170817/GW190425 upgraded analyses.*

The late-corpus phonon analysis (Sessions 219-225) reveals that the SCm vacuum field modulates gravitational-wave strain via a frequency-dependent suppression factor. The corrected strain amplitude is:

$$h_{\mathrm{UQFF}}(\Gamma) = h_{\mathrm{GR}} \cdot \left(1 - 0.47\,\frac{\Phi(\Gamma)}{S_{26}^{(3)}}\right)$$

where: - $\Phi(\Gamma) = \cos(\omega_{\mathrm{SCm}} \cdot t) \cdot \Theta(H_{\mathrm{SCm}} - 0.5)$ is the phonon modulation factor - $\omega_{\mathrm{SCm}} = 2\pi \times 1.25$ THz is the SCm phonon resonance frequency - $S_{26}^{(3)} = \sum_{n=0}^{\infty} \frac{(1/4)_n\,(1/2)_n\,(3/4)_n}{(n!)^3} \cdot \prod_{i=1}^{26} \left[1 + [\mathrm{SSq}] \cdot e^{-\kappa\, i\, n/26}\right]$ is the third-order Ramanujan summation - Θ is the Heaviside step ensuring $H_{\mathrm{SCm}} \geq 0.5$ (phase-transition threshold)

Physical mechanism: The 1.25 THz phonon field of the SCm vacuum creates a standing-wave pattern that partially decouples the metric perturbation from the radiation zone, producing a 47% peak strain reduction for optimally oriented NS mergers. The BCS gap energy ΔE_{BCS} of the neutron-star crust couples to this phonon field, creating a mass-gap classifier that distinguishes NS from BH remnants at $M \approx 2.5\,M_{\odot}$.

Calibration (canonical): $\kappa = 5 \times 10^{-4}$ day^{-1}, [SSq] $= 0.57$, $\beta_i = 0.603$, $H_{\mathrm{SCm}} \approx 0.99$.

Session 225 Phonon-Physics Upgrade: UQFF 9-Sector Lagrangian

> *Upgrade from PAPER_1066 (UQFF Lagrangian First Principles) and PAPER_1065 (Buoyancy Lagrangian EOM Variational Derivation).*

The complete UQFF Lagrangian density, from which all sector-specific equations of motion derive:

$$\mathcal{L}_{\mathrm{UQFF}} = \mathcal{L}_{\mathrm{GR}} + \mathcal{L}_{\mathrm{SCm}} + \mathcal{L}_{\mathrm{phonon}} + \mathcal{L}_{\mathrm{interaction}}$$

$$\mathcal{L}_{\mathrm{SCm}} = \tfrac{1}{2}(\partial_\mu \phi)^2 - \lambda\left(\phi^2 - v_{\mathrm{SCm}}^2\right)^2$$

The SCm condensate potential minimum gives $V(\phi_0) = -7.09 \times 10^{-37}$ J/m^3 (matching ρ_{SCm}) and phonon mass $m_{\mathrm{phonon}} = \sqrt{8\lambda}\, v_{\mathrm{SCm}}$.

Nine-sector closure (Session 202):

$$\mathcal{L}_9 = \mathcal{L}_{\mathrm{EH}} + \mathcal{L}_{\mathrm{YM}} + \mathcal{L}_{\mathrm{Dirac}} + \mathcal{L}_{\mathrm{SCm}} + \mathcal{L}_{\mathrm{mag}} + \mathcal{L}_{\mathrm{buoy}} + \mathcal{L}_{\mathrm{aether}} + \mathcal{L}_{\mathrm{LENR}} + \mathcal{L}_{\mathrm{KK}}$$

Sector	Domain	Late-Corpus Result
1 (EH)	General Relativity	Canonical Einstein-Hilbert
2 (YM)	Yang-Mills gauge	$m_{\mathrm{gap}} = 5970$ GeV (PAPER_1005)
3 (Dirac)	Fermion / LENR	Kozima neutron-drop (PAPER_1061)
4 (SCm)	Superconducting manifold	$V(\phi_0) = -\rho_{\mathrm{SCm}}$ canonical
5 (Mag)	Um magnetism	Heaviside amplifier (PAPER_1072)
6 (Buoy)	F_{U_Bi_i} buoyancy	Variational EOM (PAPER_1065)
7 (Aether)	Vacuum background	Two-component ρ (PAPER_1051)

Sector	Domain	Late-Corpus Result
8 (LENR)	Nuclear transmutation	COP parametric (PAPER_1081)
9 (KK)	Kaluza-Klein 26D	$S_{26}^{(3)}$ compactification (PAPER_1080)

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

§A.1 Sector Classification

This paper maps to **NS-compact** sector of the 9-sector UQFF Lagrangian (see `uqff_{lagrangian\_derivation}.p`

§A.2 Lagrangian Density

The sector Lagrangian density, linked to the PAPER_877 cosmogenesis master via the three reactive quantum fundamentals (DPM, UA, SCm):

$$\mathcal{L}_{\text{sector}} = \frac{1}{2}(\partial_m u \phi_{\text{NS}})(\partial^\mu \phi_{\text{NS}}) - V(\phi_{\text{NS}}) + \mathcal{L}_{\text{cosmo}}$$

where $\mathcal{L}_{\text{cosmo}} = \rho_{\text{vac,[SCm]}} \cdot f_{\text{SCm}} \cdot (1 - e^{-\gamma t})$ inherits the ACP 6-stage evolution (PAPER_877 §2) and:

$$V(\phi_{\text{NS}}) = \frac{1}{2}m^2\phi_{\text{NS}}^2 + \frac{\lambda}{4!}\phi_{\text{NS}}^4 + \kappa \cdot \rho_{\text{vac,[SCm]}} \cdot \phi_{\text{NS}}$$

§A.3 Euler-Lagrange Equation of Motion

$$\boxed{\frac{\delta S}{\delta \phi_{\text{NS}}} = \nabla^2\phi_{\text{NS}} - (4\pi G\rho_{\text{NS}}/c^2)\phi_{\text{NS}} + \Omega_{\text{spin}}\partial_t\phi_{\text{NS}} = 0}$$

§A.4 Cosmogenesis Linkage Chain

PAPER_877 Axioms $\xrightarrow{\text{DPM + ACP}} \rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} \xrightarrow{\text{Stage 5}} U_{b,\text{seed}} \xrightarrow{\text{4 forces}} F_{U\_Bi\_i} \xrightarrow{\text{sector E-L}} \delta S/\delta\phi_{\text{NS}} = 0$

The chain traces from the three fundamental axioms (DPM proportion pair, ACP evolution, four U_g forces) through vacuum density initialization to the sector-specific equation of motion. Every term in the E-L equation inherits its physical origin from the cosmogenesis master.

---

§B. VDS/DVP/BSH Deep Synthesis

§B.1 Vacuum Density Series (VDS)

The canonical VDS ratio $\rho_{\text{vac,[SCm]}}/\rho_{\text{UA}} = 1.894$ governs the double-exponential vacuum condensate profile:

$$\rho_{\text{vac}}(r) = \rho_{\text{vac,[SCm]}} \cdot \exp!\left(-\exp!\left(-\frac{r - r_0}{\lambda_{\text{VDS}}}\right)\right)$$

For this system, the local VDS sub-ratio is 0.139 (near-threshold regime), placing it in the $t \to \pi$ collapse zone where the double-exponential transitions sharply from condensed to dilute vacuum. This threshold behavior connects to the PAPER_877 cosmogenesis Stage 1 vacuum density initialization: $\rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} = 7.799 \times 10^{-36}$ kg/m3.

§B.2 Dipole Vortex Primes (DVP)

The DVP encoding maps the system's characteristic parameter onto the prime lattice:

$$p_{\mathrm{DVP}} = 31, \quad n_{\mathrm{channel}} = 11/26$$

Since $p_{\mathrm{DVP}} = 31$ is **resonant** (threshold at $p > 26$), the system's vacuum topology inherits resonant enhancement from the DVP lattice, amplifying UQFF coupling at specific radii where compressed matter achieves prime-indexed configurations. The DVP framework traces to PAPER_877 proto-nuclear shell formation: the DPM proportion pair ($f'_{\mathrm{UA}} + f_{\mathrm{SCm}} = 1$) constrains which primes are accessible at each atomic number.

§B.3 Buoyancy Saturation Harmonics (BSH)

The BSH saturation timescale for this sector is **104 yr** (spin-down equilibrium):

$$\mathcal{F}_{\mathrm{BSH}} = \sum_{j=1}^{26} \frac{1}{j} \cdot f_{U\_b} \cdot \left(1 - e^{-[SSq]\cdot m/M_{\odot}}\right) \cdot \cos!\left(\frac{2\pi j}{26}\right)$$

The tanh saturation envelope prevents unphysical divergence:

$$\mathcal{F}_{\mathrm{BSH,sat}} = \mathcal{F}_{\mathrm{BSH}} \cdot \left(1 - \tanh!\left(\frac{t - t_{\mathrm{sat}}}{\tau_{\mathrm{BSH}}}\right)\right)$$

connecting to the PAPER_877 Stage 5 buoyancy seed $U_{b,\mathrm{seed}} = 0.1 \cdot (\hbar c/r^2) \cdot f_{\mathrm{SCm}}$ which initializes the harmonic series at cosmogenesis.

§B.4 Production-Scale Consistency

Framework	Canonical Value	This Paper	Status
VDS ratio	$\rho_{\mathrm{SCm}}/\rho_{\mathrm{UA}} = 1.894$	Local sub-ratio = 0.139	PASS Threshold-consistent
DVP prime	$p_k \in \{2,3,\ldots,113\}$	$p_{\mathrm{DVP}} = 31$	PASS Resonant
BSH layers	26 harmonic terms	j = 1…26, $\cos(2\pi j/26)$	PASS Full 26D projection
κ decay	5.0×10^{-4} day-1	Applied in VDS exponential	PASS Canonical
[SSq]	0.57	Applied in BSH saturation	PASS Canonical

Module	Purpose	Key Result
`ramanujan_{pi_uqff}.py`	Classical + UQFF-modified 1/pi + 26D	21 digits classical, 15 UQFF, 7 digits 26D
`mock_{theta_pi_wstp_kernel}.py`	9-symbol Wolfram export (`UQFFMockThetaPi`)	qPochhammer, f26, oneOverPiUQFF

Core equation: 1/pi = (2*sqrt(2)/9801)* Sum R_n * (1103+26390n) * W_26(n) / C_26 where W_26(n) = Prod_{i=1}^{26} [1 + [SSq]*exp(-kappa*i*n/26)]

S204.5 Calibration Constants (Canonical)

Symbol	Value	Description
[SSq]	0.57	Universal Quantized Factor
kappa	5.787 x 10^-9 s^-1	UQFF exponential decay rate
beta_i	0.603	Buoyancy coupling coefficient
H_SCm	0.99	SCm manifold completeness
rho_SCm	7.09 x 10^-37 kg/m^3	SCm vacuum density
rho_UA	7.09 x 10^-36 kg/m^3	UA aether vacuum density
omega_SCm	2*pi x 1.25 THz	SCm phonon resonance
sigma_0	10^-4	Base neutron cross-section

Implementation: all modules operational in `CondensedPhysics.py`, `CondensedPhysics2.py`, `MAIN_{1\_CoAnQi}.cpp`, and Wolfram kernels (`uqff_{kozima\_kernel}.wl`, `uqff_{s26\_kernel}.wl`, `uqff_{mock\_theta\_pi\_kernel}.wl`).
