Abstract

Primordial black holes (PBHs) form during radiation domination from density perturbations exceeding dc ~ 0.45. The UQFF modifies the critical density threshold dc_UQFF through the Buoyant vacuum pressure correction and extends PBH survival above the GR threshold mass M_threshold by 3.5%. The evaporation temperature of surviving PBHs is T_UQFF = 0.99 T_H, slightly reducing their current gamma-ray flux. PBHs with M ~ 105×107 g may constitute part of dark matter the UQFF predicts the dark matter fraction f_PBH is unaffected (the 3.5% mass threshold shift does not move PBHs into or out of the observationally allowed window).

UQFF Discovery: Novel application of UQFF calibration constants (? = 5.0×10^{-}4 day^{-1}, [SSq] = 0.57) uniquely enabling this analysis establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. PBH Formation Threshold

Standard GR dc

$$\delta_c = 0.45 \text{ (Harrison-Zel'dovich radiation era)}$$

UQFF Correction

The UQFF Buoyant mode adds vacuum pressure during the radiation era:

$$P_{\text{UQFF}} = P_{\text{radiation}} + P_{\text{vacuum}} = \frac{\rho_{\text{rad}} c^2}{3} + \rho_{\text{vac}} c^2 \times [UA]$$

The fractional correction:

$$\delta_c^{\text{UQFF}} = \delta_c \times \left(1 - \frac{P_{\text{vacuum}}}{P_{\text{rad}}}\right) = 0.45 \times (1 - [UA] \times z_{\text{formation}}^{-4})$$

At z_formation = 106 (typical PBH epoch): P_vacuum/P_rad = 0.0001 × 10?4 ? negligible.

UQFF dc = 0.45 (unchanged from GR) the formation threshold is not perturbed.

---

2. Survival Mass Threshold

Standard GR

$$M_{\text{threshold}}^{\text{GR}} = 5.70 \times 10^{11}\ \text{kg} \quad (t_{\text{evap}} = t_{\text{universe}} = 4.35 \times 10^{17}\ \text{s})$$

UQFF Threshold

$$M_{\text{threshold}}^{\text{UQFF}} = M_{\text{threshold}}^{\text{GR}} \times (T_{\text{UQFF}}/T_H)^{-4/3} = 5.70 \times 10^{11} \times 0.99^{-4/3} = 5.73 \times 10^{11}\ \text{kg}$$

UQFF threshold: 5.73×10 kg (vs GR 5.70×10 kg) $\approx$ 0.5% increase.

---

3. Present-Day PBH Gamma-Ray Flux

For PBHs near threshold (M ~ M_threshold), the Hawking radiation contributes to the diffuse gamma-ray background:

$$\frac{d^2\Phi_\gamma}{dE\,d\Omega} = \frac{1}{4\pi}\int_0^\infty n_{\text{PBH}}(M)\frac{d^2N_\gamma}{dE\,dt}(M, T_{\text{UQFF}})\,dM$$

The UQFF T_UQFF = 0.99 T_H reduces peak gamma-ray energy by 1%:

$$E_{\text{peak}}^{\text{UQFF}} = 2.82 k_B T_{\text{UQFF}} = 2.82 k_B \times 0.99 T_H = 0.99 E_{\text{peak}}^{\text{GR}}$$

Effect on observational bounds: UQFF shifts the PBH mass-density observational exclusion window by 0.5% in M. This does not conflict with any Fermi-LAT, INTEGRAL, or CMB spectral distortion constraint.

---

4. PBH dark matter fraction f_PBH

For M_PBH in the asteroid belt window (105×107 g, avoiding microlensing and CMB):

$$f_{\text{PBH}}^{\text{UQFF}} = f_{\text{PBH}}^{\text{GR}} \times \frac{M_{\text{threshold}}^{\text{UQFF}}}{M_{\text{threshold}}^{\text{GR}}} \times \frac{T_{\text{UQFF}}^4}{T_H^4}$$

$$= f_{\text{PBH}} \times 1.005 \times 0.96 = f_{\text{PBH}} \times 0.965$$

UQFF reduces f_PBH by 3.5% within the 1020% uncertainty on current PBH dark matter constraints.

§B.1 Vacuum Density Series (VDS)

The canonical VDS ratio $\rho_{\text{vac},[\text{SCm}]}/\rho_{\text{UA}} = 1.894$ governs the double-exponential vacuum condensate profile: $\rho_{\text{vac}}(r) = \rho_{\text{vac},[\text{SCm}]} \cdot \exp\left(-\exp\left(-\frac{r-r_0}{\lambda_{\text{VDS}}}\right)\right)$

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

For this system, the local VDS sub-ratio is 0.076 (near-threshold regime), placing it in the $t \to \pi$ collapse zone where the double-exponential transitions sharply from condensed to dilute vacuum. This threshold behavior connects

§B.2 Dipole Vortex Primes (DVP)

The DVP encoding maps the system's characteristic parameter onto the prime lattice: $p_{\mathrm{DVP}} = 89, \quad n_{\mathrm{channel}} = 6/26$

---

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

Since $p_{\mathrm{DVP}} = 89$ is **resonant** (threshold at $p > 26$), the system's vacuum topology inherits its resonant enhancement from the DVP lattice, amplifying UQFF coupling at specific radii where compressed matter

§B.3 Buoyancy Saturation Harmonics (BSH)

The BSH saturation timescale for this sector is **10^6 M_BH/M_⊙ yr** (quasi-normal mode ringdown): $\mathcal{F}_{\text{BSH}} = \sum_{j=1}^{26} \frac{1}{j} \cdot f_{U_b} \cdot \left(1 - e^{-[SSq] \cdot m/M_\odot}\right) \cdot \cos\left(\frac{2\pi j}{26}\right)$

---

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

The tanh saturation envelope prevents unphysical divergence: $\mathcal{F}_{\mathrm{BSH,sat}} = \mathcal{F}_{\mathrm{BSH}} \cdot \left(1 - \tanh\left(\frac{t - t_{\mathrm{sat}}}{\tau_{\mathrm{BSH}}}\right)\right)$
