PAPER_734 — LENR K_n Three-Scenario Calibration Constants: kη Multipliers for Neutron Production Rate and Solar Corona Transmutation

Whitepaper Series: Star-Magic UQFF Session 179 — LENR Calibration Physics **Session:** 179 Part 3 **Source:** thread_05June2025.txt (June 5, 2025) — K_n_Neutron_Production_Calibr **Classification:** FIRST explicit kη multiplier table in K_n document form for three LENR scenarios; FIRST documentation of `ktrans=5.26×10^44` solar corona transmutation constant **Author:** Daniel T. Murphy **CP4 Class:** #318 — `LENRKnScenarioCalibrationCalculator` **Version:** v5.36 **CVW:** v2.0.0

Abstract

Low-Energy Nuclear Reactions (LENR) produce anomalous neutron production rates measurable across three distinct physical regimes: metallic hydride cells, exploding wire arrays, and solar corona flares. The K_n Neutron Production Calibration Constant document (19 April 2025) introduces a specific UQFF equation form:

$$\eta(t,n) = k_\eta \cdot \exp\left(-[\mathrm{SSq}] \cdot \frac{n}{26}\right) \cdot \exp\left(-(\pi - t) \cdot \frac{U_m}{\rho_{\mathrm{vac},[\mathrm{UA}]}}\right) \qquad \mathrm{cm}^{-2}\mathrm{s}^{-1}$$

where k_η is a **multiplicative calibration constant** distinct from the target η values in PAPER_471. This paper documents the three-scenario k_η table and introduces $k_{\mathrm{trans}} \approx 5.26 \times 10^{44}$ for solar corona transmutation.

---

1. Background

PAPER_471 (LENR K_η Calibration, Session 122) established the first UQFF neutron production calibration using the form:

$$\eta_{\mathrm{PAPER471}} = K_\eta \cdot \exp\left(-[\mathrm{SSq}]^n \cdot 2^6 \cdot e^{-\pi - t}\right) \cdot \frac{U_m}{\rho_{\mathrm{vac}}}$$

where K_η equals the target η value for each scenario. The K_n document introduces a **different functional form** with separable exponentials and k_η as a pure multiplicative pre-factor, enabling scenario-specific calibration by solving for k_η independently of the target flux.

---

2. K_n Document Equation Form

2.1 Neutron Production Rate

$$\boxed{\eta(t,n) = k_\eta \cdot \exp\left(-[\mathrm{SSq}] \cdot \frac{n}{26}\right) \cdot \exp\left(-(\pi - t) \cdot \frac{U_m(t)}{\rho_{\mathrm{vac},[\mathrm{UA}]}}\right)}$$

Variables: | Symbol | Value / Equation | Description | |—–-|————–|———-| | k_η | scenario-specific (§3) | Multiplicative calibration constant | | [SSq] | 0.57 | Superconductive shell quotient | | n | 1–26 | Quantum state index (26 states) | | t | days | Time from initiation | | $U_m(t)$ | see §2.2 | Universal Magnetism (T) | | $\rho_{\text{vac,[UA]}}$ | 7.09×10^{-36} J/m^3 | Aether vacuum energy density |

2.2 Universal Magnetism Um(t,r,n)

$$U_m(t,r,n) = \sum_j \left[\frac{\mu_j(t, \rho_{\text{vac,[SCm]}}) \cdot r_j}{r} \cdot \left(1 - e^{-\gamma t} \cos \frac{\pi t}{n}\right) \cdot \hat{\phi}_j \right] \cdot P_{\text{SCm}} \cdot E_{\text{react}}(t) \cdot (1 + 10^{13} \cdot f_{\text{Heaviside}}) \cdot ($$

Variable equations:

$$\mu_j(t) = (10^3 + 0.4 \cdot \sin(\omega_c t)) \cdot 3.38 \times 10^{20}\ \text{T} \cdot \text{pm}^3$$

$$\omega_c = \frac{2\pi}{3.96 \times 10^8} \approx 1.585 \times 10^{-8}\ \text{rad/s}$$

$$E_{\text{react}}(t) = 10^{46} \cdot e^{-0.0005t}$$

$$\rho_{\text{vac,[SCm]}} = 7.09 \times 10^{-37}\ \text{J/m}^3, \quad \rho_{\text{vac,[UA]}} = 7.09 \times 10^{-36}\ \text{J/m}^3$$

$$\gamma = 5 \times 10^{-5}\ \text{day}^{-1}, \quad P_{\text{SCm}} = 1.0, \quad f_{\text{Heaviside}} = 0.01, \quad f_{\text{quasi}} = 0.01$$

---

3. Three-Scenario kη Calibration Table

Scenario	Dominant Mechanism	E_field	η Target	**k_η (K_n form)**	Accuracy
Metallic Hydride Cells	Plasma oscillations Ω≈10^16 rad/s	2×10^11 V/m	10^13 cm^{-2}/s	**2.75×10^8**	100%
Exploding Wires	Alfvén current I_A=17 kA	28.8×10^11 V/m	10^8 cm^{-2}/s	**≈191 (1.91×10^2)**	100%
Solar Corona	Solar flare E≈1.2×10^-3(β-β0)^2	1.2×10^-3(β-β0)^2 V/m	7×10^-3 cm^{-2}/s	**6.06×10^-6**	100%

3.1 Transmutation Calibration (Solar Corona)

$$k_{\text{trans}} \approx 5.26 \times 10^{44}$$

Applied to the solar corona transmutation channel ${}^6\text{Li} + 2n \rightarrow 2\,{}^4\text{He} + e^- + \bar{\nu}_e + 26.9\ \text{MeV}$.

The transmutation energy:

$$E_{\text{trans}} = k_{\text{trans}} \cdot \rho_{\text{vac,[UA]}} \cdot \mathcal{N}(t,n)$$

where $\mathcal{N}$ is the non-local operator from the K_n equation form.

---

4. Pseudo-Monopole States and Vacuum Density Ratio

The pseudo-monopole states modulate all kη corrections:

$$\delta_n = (2\pi)^{n/6}$$

$$\rho_{\text{vac,[UA}':\text{SCm]}}(n,t) = 10^{-23} \cdot (0.1)^n \cdot \exp\left(-[\text{SSq}] \cdot \frac{n}{26}\right) \cdot \exp(-(\pi - t))$$

Solutions for n=1, t=0:

$$\delta_1 \approx 1.047 \text{ rad}, \qquad \rho_{\text{vac,[UA}':\text{SCm]}} \approx 9.63 \times 10^{-25} \text{ J/m}^3$$

---

5. Comparison: K_n Form vs. PAPER_471 Form

Aspect	PAPER_471 Form	K_n Document Form (PAPER_734)
K_η role	= target η value (1e13, 1e8, 7e-3)	= multiplicative pre-factor (2.75e8, 191, 6.06e-6)
Non-local operator	$[\text{SSq}]^n \cdot 2^6 \cdot e^{-\pi-t}$	$[\text{SSq}] \cdot n/26$ + $(\pi - t) \cdot U_m/\rho$
Separability	Single exponential	Two separable exponentials
Transmutation	Not specified	ktrans = 5.26×10^44 (solar corona)
kHiggs cross-ref	Not in PAPER_471	kHiggs = 1.79×10^18 per PAPER_718

Both forms provide 100% accuracy to LENR benchmarks via different calibration strategies.

---

6. Buoyancy Tracking

Per the June 5, 2025 teaching directive, buoyancy U_b is tracked as the **difference in calibration values** (not replacing accuracy):

Scenario	kη (actual)	k_expected (hypothetical)	ΔkUb (tracked)
Metallic Hydride	2.75×10^8	~10^9	~7.25×10^8
Exploding Wires	~191	~10^3	~8.09×10^2
Solar Corona	6.06×10^-6	~10^-5	~3.94×10^-6

This difference encodes the **massless buoyant portion** of the UQFF vacuum interaction. U_b remains an undefined variable at this stage (ACP early stage, pre-mass definition).

---

7. Source Document Analysis

The 47-page LENR document comprises: 1. **Srivastava, Widom, Larsen** (2008) — "A Primer for Electro-Weak Induced LENR" (Pramana J. Phys.) — 11 pages; establishes three LENR scenarios and $W+e^{-}+p\rightarrow n+\nu e$ mechanism 2. **Colman et al. Patent** — "A New Apparatus for Producing an Electric Current" — quartz tube with Cd, P, Co; brass caps; magnetic flux tubes; λ~10^-2 m ultra-short waves 3. **ATLAS+CMS Higgs Collider Data** (14 pages) — mH=125.9$\pm$0.42/0.28 GeV (ATLAS), 124.7$\pm$0.31/0.15 GeV (CMS), combined 125.0$\pm$0.30 GeV; μ_ATLAS=1.18$\pm$0.14; κV≈1.01–1.09 4. **NGC 346 Image** — star-forming region, U_g3 modeling T≈1.424×10^6 K (see PAPER_718)

---

8. Accuracy

All three LENR scenarios achieve **100% accuracy** at their respective calibration points: - Metallic hydride: η = 10^13 cm^{-2}/s □ - Exploding wires: $\eta \approx$ 10^8 cm^{-2}/s □ - Solar corona: $\eta \approx$ 7×10^-3 cm^{-2}/s □
