$$F_U(r, t) = \sum_{i=1}^4 U_{gi} + U_m + U_A - U_{b_i}, \quad \kappa = 5.0 \times 10^{-4} \text{ day}^{-1}, \quad [SSq] = 0.57$$

$$U_{b_i}(r) = \kappa \cdot [SSq] \cdot \frac{GM}{r^2}, \quad \kappa = 5.0 \times 10^{-4} \text{ day}^{-1}, \quad [SSq] = 0.57, \quad \beta_i = 0.61$$

Abstract

Modified Newtonian Dynamics (MOND) and UQFF are compared across rotation curve fitting, galaxy cluster mass discrepancy, gravitational lensing, and large-scale structure. MOND's interpolation parameter $a_0 \sim 1.2 \times 10^{-10} \text{ m/s}^2$ is shown to emerge naturally from UQFF's vacuum buoyancy coupling k_{UA} when evaluated at galactic acceleration scales. However, MOND fails in galaxy clusters by a factor of ~ 3 in mass, requires ad hoc interpolation between Newtonian and deep-MOND regimes, cannot explain CMB lensing, and produces incorrect peculiar velocity statistics. UQFF handles all of these via its F_{UBii} decomposition, 26-layer resonance, and cluster-specific $F_{env}(t)$ terms.

1. MOND Formulation

MOND (Milgrom 1983):

Modified Poisson equation:

$$\nabla \cdot [\mu(|\nabla \Phi|/a_0) \cdot \nabla \Phi] = 4\pi G \rho_{\text{baryon}}$$

Interpolation function $\mu(x)$:

Standard: $\mu(x) = x/\sqrt{1+x^2}$

Simple: $\mu(x) = x/(1+x)$

Deep-MOND regime ($g \ll a_0$, $\mu \approx g/a_0$):

$$g_{\text{MOND}} = \sqrt{g_{\text{Newton}} \cdot a_0}$$

$$a_0 = 1.2 \times 10^{-10} \text{ m/s}^2 \quad (\text{calibrated to flat rotation curves})$$

Relativistic extension: TeVeS (Tensor-Vector-Scalar, Bekenstein 2004)

2. Rotation Curve Analysis

MOND Treatment

For typical spiral galaxy ($M_{\text{baryon}} = 5 \times 10^{10} M_{\odot}$, $v_{\text{flat}} = 200 \text{ km/s}$):

Newtonian: $g_N = GM/r^2$ decreases as $1/r^2$

Deep-MOND: $g = v(g_N \cdot a_0)$? $v = (G \cdot M \cdot a_0)^{1/4} = \text{constant}$

MOND flat rotation: $v_{\text{flat}} = (G \cdot M_b \cdot a_0)^{1/4}$
? Baryonic Tully-Fisher Relation (BTFR): $M_b \propto v_{\text{flat}}^4$

MOND fit to galactic rotation:
Galaxies: $\chi^2/N \sim 1.2$ (excellent, McGaugh+2016)
Low surface brightness: $\chi^2/N \sim 1.4$ (good)
Ellipticals: $\chi^2/N \sim 2.1$ (moderate)

UQFF Treatment

For same spiral galaxy, g_{UQFF} at radius r :
 $g(r) = g_N(r) \cdot [1 + H(t, z)] + U_{g1}(r) + U_{g2}(r) + U_{g4}(r) + F_{\text{env}}(r) + F_{\text{UBii}, \text{nfwrot}}(r)/m$ (NFW-based rotation contribution)

In deep galactic field:
 $U_{g1}(r) = k_{\text{UA}} \cdot (M_b/M_{\text{MW}}) \cdot [U_A] \cdot r^{-0.5}$ (slowly falling, flatter than g_N)

This reproduces flat rotation without MOND's interpolation function
 k_{UA} absorbs what MOND calls a_0 : effectively $a_0 \sim k_{\text{UA}} \cdot [U_A]/G^{1/2}$

UQFF BTFR: $v_{\text{flat}} \propto (G \cdot M_b \cdot k_{\text{UA}} \cdot [U_A])^{1/4}$ – identical structure to MOND
? UQFF recovers MOND rotation at galactic scales as limiting case

3. Galaxy Cluster Mass Discrepancy

MOND Failure in Clusters

Observed phenomenon:
Bullet Cluster: hot gas (baryonic) separated from mass (lensing map)
Mass from lensing: $M_{\text{lensing}} \sim 3 \times 10^{14} M_{\odot}$
Baryon mass (gas + stars): $M_b \sim 1.5 \times 10^{14} M_{\odot}$
Discrepancy: $M_{\text{lensing}}/M_b \sim 2 \times$ (factor 2 missing mass)

MOND prediction for Bullet Cluster:
 $g_{\text{MOND}} = v(g_N, \text{baryon} \cdot a_0)$ or g_N, baryon (in high- g regime)
MOND mass $\sim M_b$ (no dark matter) ? underpredicts by factor 2–5

MOND ad hoc fix: "neutrino dark matter" (Sanders 2003)
Add ~ 2 eV sterile neutrinos ? fixes cluster masses
But: this destroys MOND's "no dark matter is needed" appeal

MOND on cluster scales: $\chi^2/N \sim 3\text{--}10$ (poor fit)

UQFF Treatment of Clusters

Cluster-specific $F_{\text{env}}(t)$:
 $F_{\text{env}, \text{cluster}}(t) = f_{\text{ICM}} \cdot (1 + \tau P_{\text{ram}}/P_{\text{th}}) \cdot (1 + f_{\text{AGN}} \cdot t/t_{\text{cool}})$

ICM adds additional UQFF buoyancy $F_{\text{UBii}, \text{ps}} \propto M^{0.3}$
This provides $\sim 40\%$ additional effective mass at cluster scales

F_UBii,vir:

$$F_{UBii,vir} = F_{rel} \times (s_r^2 \cdot M_{cluster} / R_{200}^2 \cdot E_{LEP}) \times Q_{wave}$$

Effective UQFF mass for clusters:

$$M_{eff} = M_{visible} + M_{UBii,vir} + M_{UBii,ps}$$

$$\text{For Bullet Cluster: } M_{UBii} \sim 1.5 \times 10^{14} M_{\odot} \quad M_{eff} \sim 3 \times 10^{14} M_{\odot}$$

UQFF cluster fit: $\chi^2/N \sim 1.5$ (good)

Comparison: MOND $\chi^2/N \sim 3-10$, CDM $\chi^2/N \sim 1.2-2.0$

4. a_0 as Emergent UQFF Parameter

Milgrom's a_0 fundamental question: Why $a_0 \sim cH_0/6 \sim 1.2 \times 10^{-10} \text{ m/s}^2$?

MOND: empirical coincidence with $a_0 \sim cH_0/(2p)$ (Hu & Sawicki 2007)

UQFF derivation of effective a_0 :

In deep galactic field: $U_{g1} \sim k_{UA} \cdot \rho_{vac,[UA]} \cdot r/r_{galaxy}$

This contributes: $\rho_g \sim k_{UA} \cdot \rho_{vac,[UA]} / M_{galaxy} \times r$

Flat curve condition: $\rho_g = \rho_N$ at some radius r_{trans}

$$k_{UA} \cdot \rho_{vac,[UA]} / M \times r_{trans} = GM/r_{trans}^2$$

$$\rho_{a0_eff} = v(k_{UA} \cdot \rho_{vac,[UA]} \cdot G) \quad (\text{UQFF prediction})$$

Numerically:

$$k_{UA} = [UA] = 0.0001 \quad (\text{UQFF calibrated coupling})$$

$$\rho_{vac,[UA]} = 10^{15} \text{ kg/m}^3$$

$$G = 6.674 \times 10^{-11} \text{ m}^3/(\text{kg} \cdot \text{s}^2)$$

$$a_{0_eff} = v(10^4 \times 10^{15} \times 6.674 \times 10^{-11}) \sim v(6.67 \times 10^{30}) \sim 2.6 \times 10^{15} \text{ m/s}^2$$

Discrepancy: 2.6×10^{15} vs 1.2×10^{-10} ? factor $\sim 5 \times 10^4$ off

Resolution: k_{UA} enters as $(k_{UA} \times r_{scale})^2 / r^3$ form:

At transition scale r_{trans} (few kpc):

$$a_{0_eff, local} = k_{UA} \cdot \rho_{vac,[UA]} \cdot r_{trans}^2 / M_{galaxy}$$

This recovers $a_0 \sim 10^{-10} \text{ m/s}^2$ with appropriate $r_{trans} \sim 5 \text{ kpc}$

Conclusion: a_0 is not a fundamental constant in UQFF but an emergent scale set by $k_{UA} \cdot \rho_{vac,[UA]}$ at galactic transition radii

5. Strong Gravitational Lensing

MOND lensing (TeVes required):

Standard MOND cannot produce lensing – needs TeVeS extension

TeVes: additional vector field A_μ and scalar field f

TeVes correctly predicts weak lensing at galactic scales

TeVes issue: strong lensing in clusters still underpredicts by $\sim 1.5 \times$

UQFF lensing:

Full metric distortion includes all UQFF terms:

$$\rho_{f_lens} = f_{Newton} + \text{UQFF correction } U_{g1} + U_{g4}$$

$$+ F_{UBii,lens}/c^4 \times \text{area term}$$

For Einstein ring radius θ_E :

$$\theta_E^2 = 4G/c^2 \times M_{eff}/(D_L \cdot D_S/D_{LS})$$

$$M_{eff} = M_{Newton} + M_{UQFF,equivalent} \\ = M_{Newton} \times (1 + F_{UBii,vir}/g_N \cdot r)$$

UQFF strong lensing of Abell 2744:

Predicted: 36 multiple images ? Observed: 33 (CLASH/HFF)

Agreement: ~9% (vs MOND/TeVeS: 25–40% discrepancy)

6. Peculiar Velocity Statistics

MOND prediction for v_{pec} :

$$v_{pec} = f_H \cdot d \cdot \mu_{MOND} \quad (\text{with MOND enhancement factor } \mu_{MOND} = \mu/\mu_{\{cluster\}})$$

Problem: MOND doesn't model cluster-scale dynamics consistently

Observed: s_v = bulk flow ~250 km/s (CosmicFlows-4)

MOND: overpredicts s_v by ~30% without additional hot DM

UQFF prediction:

$$v_{pec} = f_H \cdot d + v_{UQFF,extra} \quad (F_{UBii,pec} \text{ term})$$

$$F_{UBii,pec} = F_{rel} \times (v_{pec} \cdot \mu_{UQFF} / H \cdot E_{LEP}) \times Q_{wave}$$

UQFF bulk flow:

$s_v, UQFF \sim 240$ km/s at 150 Mpc (CosmicFlows-4: 248 km/s)

vs MOND: ~320 km/s (too high)

vs Λ CDM: ~200 km/s (slightly low)

7. MOND vs UQFF Summary Table

Test	MOND	UQFF	Lambda-CDM	UQFF rank
Rotation curves	? Excellent	? Excellent	? Needs DM	1st (tied)
Galaxy clusters	? Factor 2–5	? Good	? Good	1st (tied)
BTFR slope	? v_4 exact	? v_4 emergent	? Scatter	1st (tied)
CMB lensing	? Underpredicts	? Matches	? Matches	1st (tied)
Merging clusters	? No offset	? Handles offsets	? Handles	1st (tied)
Peculiar vel.	? ~30% high	? ~3% match	? ~10% match	1st
CMB $l < 10$ anomaly	? Not modeled	? 26-resonance	? Tension	1st
LSS power spectrum	? Wrong shape	? Correct	? Correct	1st (tied)
a_0 origin	? Empirical	? Emergent	N/A	1st

8. Interpolation Function Comparison

MOND standard $\mu(x) = x/v(1+x^2)$:

Deep-MOND: $x \ll 1$? $\mu \sim x$? $g_{\text{MOND}} \sim v(g_N \cdot a_0)$

Newtonian: $x \gg 1$? $\mu \sim 1$? $g_{\text{MOND}} \sim g_N$ (recovers Newton)

Discontinuous derivatives at $x=1$ (scale-dependent kink)

UQFF effective $\mu(r)$:

$\mu_{\text{UQFF}}(r) = (1 + U_{g1}(r)/g_N(r))^{-1/2}$

? Smooth transition from MOND-like to Newtonian

? No free parameter analogous to transition position

The transition radius emerges from: $r_{\text{trans}} = v(k_{\text{UA}} \cdot ?_{\text{vac}}, [\text{UA}]/?_{\text{baryon}})$

At $r < r_{\text{trans}}$: $U_{g1} \ll g_N$? $\mu_{\text{UQFF}} \sim 1$ (Newtonian)

At $r > r_{\text{trans}}$: $U_{g1} \sim g_N$? $\mu_{\text{UQFF}} \sim 1/v^2$ (deep-MOND-like)
