

PAPER_444 — Hubble Ultra Deep Field “Galaxies Galore”: Per-System MUGE at Cosmic Scale $z=3.5$

Source: grok_share_68eb34022.txt — Document 17: “Master Universal Gravity Equation_HUDF_Galaxies_Galore_03May2025.docx” (lines 5154–5538) **Session:** 119 **CP4 Class:** HUDFGalaxiesGaloreMUGE_CosmicScale_HighRedshift_Calculator (#99)

1. Overview

PAPER_444 delivers the **complete per-system MUGE** for the Hubble Ultra Deep Field (HUDF) — representing the cosmic field around epoch $z \approx 3.5$, total mass $M_0 = 10^{12} M_\odot$, FoV extent $r = 1.3 \times 10^{11} \text{ ly} = 1.230 \times 10^{27} \text{ m}$ (co-moving scale of the UDF at co-moving depth to $z \sim 7$). Magnetic field $B = 10^{-10} \text{ T}$ (CMB-era primordial seed field — the weakest in the per-system series).

Novel claim (Q1): First UQFF MUGE representing a **full cosmic survey scale** — the HUDF is not a single object but a cosmological field spanning ~ 10 billion years of lookback time. PAPER_444 introduces the **cosmic interaction boost** $I(t) = 0.05 e^{-t/\tau_{\text{inter}}}$ (weaker than Antennae’s 10% because interactions in the UDF are stochastically averaged over ~ 3000 galaxies), applied as $(1 + I(t))$ to T_1 and T_2 . The $z_{\text{avg}} = 3.5$ Einstein expansion sets $H(z) \approx 1.201 \times 10^{-17} \text{ s}^{-1}$ — the largest $H(z)$ in the per-system series — and $B = 10^{-10} \text{ T}$ is the **smallest magnetic field** among all 17 documents.

2. System Parameters

Parameter	Symbol	Value
Co-moving field mass	M_0	$10^{12} M_\odot = 1.989 \times 10^{42} \text{ kg}$
Co-moving FoV scale	r	$1.3 \times 10^{11} \text{ ly}$ $= 1.230 \times 10^{27} \text{ m}$
Mean redshift	z_{avg}	3.5
$H(z)$		$H_0 \sqrt{\Omega_m (1+z)^3 + \Omega_\Lambda}$
$H(z = 3.5)$		$\approx 370.6 \text{ km/s/Mpc}$ $= 1.201 \times 10^{-17} \text{ s}^{-1}$
Primordial B field	B	10^{-10} T
SFR factor	SFR_f	1.0 (normalized)
SF timescale	τ_{SF}	$1 \text{ Gyr} = 3.156 \times 10^{16} \text{ s}$
Interaction factor	I_0	0.05
Interaction timescale	τ_{inter}	$1 \text{ Gyr} = 3.156 \times 10^{16} \text{ s}$
Wind density	ρ_w	10^{-22} kg/m^3 (early universe, lower density)
Wind velocity	v_w	10^6 m/s
Fluid density	ρ_f	10^{-22} kg/m^3

3. Cosmological H(z) Computation

$$\begin{aligned}
H(z = 3.5) &= H_0 \sqrt{\Omega_m (1 + z_{\text{avg}})^3 + \Omega_\Lambda} \\
&= 70 \text{ km/s/Mpc} \sqrt{0.3 \times (4.5)^3 + 0.7} \\
&= 70 \sqrt{0.3 \times 91.125 + 0.7} = 70 \sqrt{27.3375 + 0.7} = 70 \sqrt{28.0375} \\
&= 70 \times 5.295 = 370.6 \text{ km/s/Mpc}
\end{aligned}$$

$$H(z = 3.5) = \frac{370.6 \times 10^3}{3.086 \times 10^{22}} \approx 1.201 \times 10^{-17} \text{ s}^{-1}$$

This is $\approx 5.5 \times$ larger than the local $H_0 = 2.184 \times 10^{-18} \text{ s}^{-1}$ — the Hubble drag term $H(z)t$ is commensurately larger at high- z .

4. Time-Dependent Functions

Mass with cosmic SF:

$$M(t) = M_0 (1 + \text{SFR}_f \cdot e^{-t/\tau_{\text{SF}}}) = M_0 (1 + e^{-t/\tau_{\text{SF}}})$$

At $t = 0$: $M(0) = 2M_0 = 3.978 \times 10^{42} \text{ kg}$ (field actively forming stars)

At $t = 1 \text{ Gyr}$: $M = M_0(1 + 1/e) \approx 1.368M_0$

At $t = 3 \text{ Gyr}$: $M \approx 1.05M_0$ (star formation essentially complete)

Cosmic interaction boost:

$$I(t) = 0.05 e^{-t/\tau_{\text{inter}}}$$

At $t = 0$: $I = 0.05$ — 5% boost from early-universe elevated merger/interaction rate

At $t = 1 \text{ Gyr}$: $I = 0.0184$ — interaction rate declining as cosmic merger rate falls

At $t = 3 \text{ Gyr}$: $I \approx 0.0025$ — essentially gone by cosmic noon ($z \sim 2$)

5. Complete 10-Term MUGE

$$g_{\text{HUDF}}(r, t) = T_1(1 + I) + T_2(1 + I) + T_3 + T_4 + T_5 + T_6 + T_7 + T_8 + T_9 + T_{10}$$

T1 — Newtonian + H(z)t + B + interaction:

$$T_1 = \frac{GM(t)}{r^2} (1 + H(z)t) (1 - B/B_{\text{crit}}) (1 + I(t))$$

$$\frac{GM_0}{r^2} = \frac{6.674 \times 10^{-11} \times 1.989 \times 10^{42}}{(1.230 \times 10^{27})^2} = \frac{1.327 \times 10^{32}}{1.513 \times 10^{54}} \approx 8.77 \times 10^{-23} \text{ m/s}^2$$

$$T_1(t = 0) = \frac{GM(0)}{r^2} (1 + I_0) = \frac{6.674 \times 10^{-11} \times 3.978 \times 10^{42}}{1.513 \times 10^{54}} \times 1.05 \approx 1.84 \times 10^{-22} \times 1.05 \approx 1.93 \times 10^{-22} \text{ m/s}^2$$

T3 — Λ dark energy (large at co-moving scales):

$$T_3 = \frac{\Lambda c^2}{3} r = \frac{1.11 \times 10^{-52} \times 9 \times 10^{16}}{3} \times 1.230 \times 10^{27} \approx 4.11 \times 10^{-9} \text{ m/s}^2$$

Note: At cosmic co-moving scale $r = 1.23 \times 10^{27}$ m, the cosmological constant term becomes the **third largest contribution**.

T2 — UQFF Ug with interaction:

$$T_2 = 2 \times \frac{GM(0)}{r^2} \times f_{\text{TRZ}} \times (1 + I_0) \approx 2 \times 1.84 \times 10^{-22} \times 1.1 \times 1.05 \approx 4.24 \times 10^{-22} \text{ m/s}^2$$

T9 — Early-universe galactic wind:

$$T_9 = \frac{\rho_w v_w^2}{\rho_f \cdot r} = \frac{10^{-22} \times 10^{12}}{10^{-22} \times 1.230 \times 10^{27}} = \frac{10^{12}}{1.230 \times 10^{27}} \approx 8.13 \times 10^{-16} \text{ m/s}^2 \quad [\text{negligible}]$$

6. Canonical Numerical Result

At $t = 0$ (redshift $z = 3.5$, early universe):

Term	Value (m/s ²)	Fraction
T_3 Λ (cosmological)	4.11×10^{-9}	$\gg$ all other terms
T_1 Newtonian $\times (1+I)$	1.93×10^{-22}	negligible
T_2 UQFF $\times (1+I)$	4.24×10^{-22}	negligible
T_9 Wind	8.13×10^{-16}	trace

$$\boxed{g_{\text{HUDEF}}(t=0) \approx 4.11 \times 10^{-9} \text{ m/s}^2} \quad [\Lambda \text{ cosmological term dominant at co-moving scale}]$$

Remark — Λ dominance at cosmic scale: This result is the **first occurrence in the 17-paper series** where the dark energy (T_3) term dominates over all other gravitational terms. At co-moving $r = 10^{27}$ m, T_3 exceeds T_1 by 13 orders of magnitude. This reflects the HUDEF FoV being a cosmological scale — the MUGE correctly predicts that dark energy governs on scales larger than the matter power spectrum coherence length.

Interaction boost contribution: $I_0 = 0.05 \Rightarrow 5\%$ of T_1 :

$$\Delta g_I = 0.05 \times 1.84 \times 10^{-22} \approx 9.2 \times 10^{-24} \text{ m/s}^2$$

7. Uniqueness vs Prior Papers

Prior Paper	Overlap	New in PAPER_444
PAPER_441 (Antennae)	$I(t)$ boost	$I_0 = 0.05$ vs 0.1, $\tau = 1$ Gyr vs 400 Myr, cosmic avg
All others	Local/cluster	Only paper with $z > 1$
None	T_3 dominance	First paper where Λ term is THE dominant term
None	$H(z) = 1.2 \times 10^{-17} \text{ s}^{-1}$	Highest $H(z)$ in per-system series
None	$B = 10^{-10} \text{ T}$	Weakest magnetic field — primordial seed

8. Comparison to Standard Model

Cosmological N-body simulations (IllustrisTNG, EAGLE) model the UDF statistically, not as individual per-system physics. The SM treats dark energy as a negative-pressure background fluid ($w = -1$) uniformly accelerating expansion. UQFF re-parameterizes Λ as the T_3 term in the gravitational field equation, making its dominance at cosmic scale explicit and calculable per-system. The SF mass evolution $M(t) = M_0(1 + e^{-t/\tau_{\text{SF}}})$ matches the $z \sim 3.5$ “cosmic noon” star formation peak seen in Madau-Dickinson curve — but expressed as a direct mass multiplier on the UQFF gravitational terms rather than a statistical ensemble rate.

9. Testable Predictions

Q5 Prediction 1: $1 + H(z = 3.5) \cdot t$ for $t = 10^{16} \text{ s}$ (0.32 Gyr): $H(z)t = 1.201 \times 10^{-17} \times 10^{16} = 0.1201$, predicting 12% Hubble-drag enhancement of T_1 within the first 300 Myr after $z = 3.5$. UQFF predicts this as a 12% excess in the power spectrum amplitude at $k \sim 0.1 \text{ Mpc}^{-1}$ accessible in JWST/NIRCam deep-field power spectrum analyses of JADES-Deep-GOODS-S.

Q5 Prediction 2: $I_0 = 0.05$ with $\tau_{\text{inter}} = 1$ Gyr predicts that the galaxy pair fraction at $z = 3.5$ provides a 5% gravitational enhancement averaged over the UDF field — declining to $\sim 0.5\%$ by $z \sim 1$ ($t \sim 3\tau$). Observable as a $\Delta n(z)$ excess in close galaxy pair counts ($r_{\text{proj}} < 30 \text{ kpc}$) in HUDF WFC3/ACS mosaics: specifically, 5% more merging pairs at $z = 3.5$ than single-disk galaxies relative to $z = 1$ — testable via morphological classification with JWST/CEERS or COSMOS-Web.

Q5 Prediction 3: $B = 10^{-10} \text{ T}$ (primordial seed field at $z = 3.5$) predicts that the Faraday rotation measure (RM) averaged over UDF lines of sight is $(1/B_{\text{crit}}) \times B \approx 2.27 \times 10^{-24}$ — the gravitational suppression factor is completely negligible, meaning the UQFF U_g at $z = 3.5$ operates at full strength ($f_B \approx 1.0000$). This predicts no magnetic-field suppression of early structure formation — testable via SKA RM synthesis maps of UDF field radio sources at $z > 3$.
