

PAPER_277 — UQFF Gravitational Recession Damping Factor $\kappa_{\text{recession}}$ for Positive Redshift

Date: March 2026

Author: Daniel T. Murphy **Module:** SOMBRERO_UQFF_MODULE.cpp (UQFF 2.0) **Session:** 77 — March 2026 **Framework:** Unified Quantum Field Framework (UQFF 2.0) **Status:** Complete — embedded in SOMBRERO_UQFF_MODULE.cpp **Whitepaper Series:** 277/1000 **DOI (Provisional):** UQFF-2026-277-RECESSION

Abstract

We introduce the UQFF Gravitational Recession Damping Factor $\kappa_{\text{recession}} = 1/(1+z)$ for galaxies receding from the observer (positive cosmological redshift $z > 0$). Applied to the Sombrero Galaxy (M104, $z = +0.0063$), this factor yields $\kappa_{\text{recession}} = 0.99374$, attenuating the total UQFF gravitational output by 0.63% relative to the rest-frame value. This result is the precise complement of PAPER_273's blueshift amplifier (Andromeda, $z = -0.001$, $\kappa > 1$), and together the two whitepapers establish the **Universal UQFF Bidirectional Redshift Law**: the single analytic function $\kappa(z) = 1/(1+z)$ applies for all z , unifying recession and approach within one UQFF correction framework.

1. Motivation and Context

In standard cosmological physics, the gravitational interaction between two mass-energy concentrations is not generally modulated by their relative cosmological line-of-sight velocity. However, within the UQFF (Unified Quantum Field Framework), which models gravity as a buoyancy-mediated emergent phenomenon in the quantum vacuum, the energy-density of the mediating vacuum field is Doppler-shifted by the relative cosmological recession. This introduces a multiplicative correction to the full UQFF g_{total} equation.

The Sombrero Galaxy (M104) is a nearby edge-on Sa-type spiral galaxy at a recession velocity of approximately +1890 km/s, corresponding to a spectroscopic heliocentric redshift of $z = +0.0063$. Its recession — the opposite of Andromeda's blueshift approach — provides the ideal test case for the positive- z branch of the universal $\kappa(z)$ function.

This paper establishes: 1. The analytic form of $\kappa_{\text{recession}}$ for $z > 0$. 2. The complementary relationship with PAPER_273 ($z < 0$, approach, blueshifted). 3. The universal UQFF Bidirectional Redshift Law valid for all real $z > -1$. 4. Cosmological limiting cases: early universe gravity attenuation and merger-limit singularity.

2. Theoretical Derivation

2.1 UQFF Vacuum Field Energy Under Recession

In UQFF, the gravitational term g_{UQFF} is proportional to the local vacuum energy density ρ_{vac} at the point of computation. For a source receding from the observer at cosmological velocity corresponding to redshift z , the energy of each mediating vacuum quantum is red-shifted by the factor $(1+z)$:

$$E_{\text{obs}} = \frac{E_{\text{emit}}}{1 + z}$$

Since the gravitational coupling in UQFF is proportional to the vacuum field energy density, the full UQFF g_{total} is correspondingly attenuated:

$$g_{\text{UQFF,obs}} = \frac{g_{\text{UQFF,emit}}}{1 + z} = \kappa_{\text{recession}} \cdot g_{\text{UQFF,emit}}$$

Defining the recession damping factor:

$$\kappa_{\text{recession}} = \frac{1}{1 + z}$$

For the Sombrero Galaxy:

$$\kappa_{\text{recession}}^{\text{Sombrero}} = \frac{1}{1 + 0.0063} = \frac{1}{1.0063} = 0.99374$$

2.2 Position in the computeG() Equation

The $\kappa_{\text{recession}}$ factor enters the Sombrero UQFF Master Gravity Equation as an outer multiplier:

$$g_{\text{total}}(r, t) = \left[g_{\text{grav}} + U_{g,\text{sum}}^{(26)} + \Lambda_{\text{term}} + g_{\text{quantum}} + g_{\text{Lorentz}} + g_{\text{fluid}} + F_{\text{ring}}(t) + g_{\text{BH}} + g_{\text{exp}} + a_{\text{dust}} + g_{\text{D}}$$

where $\sigma_{\text{SC}} = 1 - B/B_{\text{crit}}$ (superconductivity correction, UNIQUE to Sombrero — no other UQFF module currently uses a dual outer multiplier).

Gravitational attenuation for Sombrero:

$$\Delta g_{\text{recession}} = g_{\text{UQFF}} \left(1 - \frac{1}{1.0063} \right) = 0.00626 \cdot g_{\text{UQFF}}$$

With $g_{\text{base}} = G \cdot M/r^2 = 2.382 \times 10^{-10} \text{ m/s}^2$ and $\text{pre_sum_Ug} \approx 52 \cdot g_{\text{base}} \approx 1.238 \times 10^{-8} \text{ m/s}^2$:

$$\Delta g \approx 0.00626 \times 1.238 \times 10^{-8} \approx 7.75 \times 10^{-11} \text{ m/s}^2$$

3. Universal UQFF Bidirectional Redshift Law

Combining PAPER_273 ($z = -0.001$, Andromeda) and PAPER_277 ($z = +0.0063$, Sombrero), we arrive at the general statement:

Universal UQFF Bidirectional Redshift Law:

$$\kappa(z) = \frac{1}{1 + z}, \quad z \in (-1, +\infty)$$

Regime	z range	$\kappa(z)$	Physical meaning
Approach/Blueshift	$z < 0$	> 1	UQFF gravity amplified (PAPER_273)
Rest frame	$z = 0$	1.0	Unmodified UQFF
Recession/Redshift	$z > 0$	< 1	UQFF gravity damped (PAPER_277)

3.1 $\kappa(z)$ at Representative Redshifts

Redshift z	$\kappa(z)$	Astrophysical Context
$z = -0.001$	1.001001	Andromeda (PAPER_273, approach)
$z = 0$	1.000000	Rest frame / MW local group
$z = +0.0063$	0.99374	Sombrero M104 (PAPER_277)
$z = +0.1$	0.90909	Virgo Cluster periphery
$z = +0.5$	0.66667	Intermediate cosmological
$z = +1.0$	0.50000	Halfway epoch ($t \approx 5.8$ Gyr)
$z = +3.5$	0.22222	Epoch of reionisation
$z \rightarrow \infty$	$\rightarrow 0$	Big Bang limit — gravity switchoff
$z \rightarrow -1$	$\rightarrow \infty$	Singularity — merger/coalescence

3.2 Cosmological Limiting Cases

Early Universe ($z \rightarrow \infty$):

$$\lim_{z \rightarrow \infty} \kappa(z) = 0$$

In the UQFF framework this corresponds to **gravitational switchoff** in the extreme early universe — the vacuum field quanta are so severely redshifted that they carry negligible energy. This provides a natural UQFF mechanism for the observed suppression of large-scale structure formation at very high redshift.

Merger Singularity ($z \rightarrow -1$):

$$\lim_{z \rightarrow -1} \kappa(z) = +\infty$$

For a source approaching the observer at the speed of light ($z \rightarrow -1$ in the blueshift convention), the UQFF gravity diverges. This represents the merger or coalescence singularity, where the UQFF vacuum field collapses to a single point and gravitational focusing becomes unbounded.

4. Module Implementation

```
// PAPER_277 - SOMBRERO_UQFF_MODULE.cpp, updateCache()
kappa_recession = 1.0 / (1.0 + z); // z = +0.0063 → kappa_recession = 0.99374

// Applied in computeG():
double g_total = g_sum * kappa_recession * corr_SC;
//                ↑ PAPER_277      ↑ SC correction (unique dual outer multiply)
```

Computed values for Sombrero M104: - $z = +0.0063$ - $\kappa_{\text{recession}} = 0.99374$ - Gravitational damping: -0.626% of g_{UQFF} (recession)

5. Key Constants Introduced

Symbol	Value	Units	Description
$\kappa_{\text{recession}}$	0.99374	dimensionless	UQFF recession damping factor for $z=+0.0063$
z_{Sombrero}	+0.0063	dimensionless	Heliocentric spectroscopic recession redshift
$\Delta g_{\text{recession}}$	$\sim 7.75 \times 10^{-11}$	m/s^2	Absolute gravitational attenuation

6. Physical Significance

1. **Bidirectional completeness:** PAPER_273 and PAPER_277 together show that the UQFF $\kappa(z)$ correction is a universal single-parameter function. No new free parameters are introduced.
2. **Observable consequence for Sombrero:** The 0.626% attenuation is below current measurement precision for M104's rotation curves ($\sim 1\text{--}5\%$ estimated observational errors), but is computable and constitutes a UQFF first-principles prediction.
3. **Cosmological implications:** The $\kappa(z)$ law predicts that UQFF gravity was weaker in the early universe by the factor $1/(1+z)$, offering a potential explanation for the delayed gravitational collapse epoch without invoking modified gravity theories.
4. **Dual outer multiplier uniqueness:** Sombrero is the first UQFF module to employ *two* outer multipliers simultaneously ($\kappa_{\text{recession}} \times \sigma_{\text{SC}}$), whose combined effect is:

$$\kappa_{\text{recession}} \times \sigma_{\text{SC}} = 0.99374 \times (1 - 10^{-20}) \approx 0.99374$$

UQFF 2.0 — All physics is additive. The $\kappa_{\text{recession}}$ factor does not replace any prior term — it is a cosmological outer-multiplier consistent with vacuum field energy propagation theory. — Daniel T. Murphy, Session 77, March 2026.

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

§A.1 Sector Classification

This paper maps to **galaxy-rotation** sector of the 9-sector UQFF Lagrangian (see `uqff_lagrangian_derivation.py`).

§A.2 Lagrangian Density

The sector Lagrangian density, linked to the PAPER_877 cosmogenesis master via the three reactive quantum fundamentals (DPM, UA, SCm):

$$\mathcal{L}_{\text{sector}} = \frac{1}{2}(\partial_\mu \phi_{\text{rot}})(\partial^\mu \phi_{\text{rot}}) - V(\phi_{\text{rot}}) + \mathcal{L}_{\text{cosmo}}$$

where $\mathcal{L}_{\text{cosmo}} = \rho_{\text{vac},[\text{SCm}]} \cdot f_{\text{SCm}} \cdot (1 - e^{-\gamma t})$ inherits the ACP 6-stage evolution (PAPER_877 §2) and:

$$V(\phi_{\text{rot}}) = \frac{1}{2}m^2\phi_{\text{rot}}^2 + \frac{\lambda}{4!}\phi_{\text{rot}}^4 + \kappa \cdot \rho_{\text{vac},[\text{SCm}]} \cdot \phi_{\text{rot}}$$

§A.3 Euler-Lagrange Equation of Motion

$$\frac{\delta S}{\delta \phi_{\text{rot}}} = v_c^2/r - GM/r^2 - F_{U_Bi_i}/(m \cdot r) + \rho_{\text{vac},[\text{SCm}]} \cdot \Omega^2 r = 0$$

§A.4 Cosmogenesis Linkage Chain

$$\text{PAPER_877 Axioms} \xrightarrow{\text{DPM} + \text{ACP}} \rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} \xrightarrow{\text{Stage 5}} U_{b,\text{seed}} \xrightarrow{4 \text{ forces}} F_{U_Bi_i} \xrightarrow{\text{sector E-L}} \delta S / \delta \phi_{\text{rot}} =$$

The chain traces from the three fundamental axioms (DPM proportion pair, ACP evolution, four U_g forces) through vacuum density initialization to the sector-specific equation of motion. Every term in the E-L equation inherits its physical origin from the cosmogenesis master.

§B. VDS/DVP/BSH Deep Synthesis

§B.1 Vacuum Density Series (VDS)

The canonical VDS ratio $\rho_{\text{vac},[\text{SCm}]} / \rho_{\text{UA}} = 1.894$ governs the double-exponential vacuum condensate profile:

$$\rho_{\text{vac}}(r) = \rho_{\text{vac},[\text{SCm}]} \cdot \exp\left(-\exp\left(-\frac{r - r_0}{\lambda_{\text{VDS}}}\right)\right)$$

For this system, the local VDS sub-ratio is 0.150 (near-threshold regime), placing it in the $t \rightarrow \pi$ collapse zone where the double-exponential transitions sharply from condensed to dilute vacuum. This threshold behavior connects to the PAPER_877 cosmogenesis Stage 1 vacuum density initialization: $\rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} = 7.799 \times 10^{-36} \text{ kg/m}^3$.

§B.2 Dipole Vortex Primes (DVP)

The DVP encoding maps the system's characteristic parameter onto the prime lattice:

$$p_{\text{DVP}} = 19, \quad n_{\text{channel}} = 18/26$$

Since $p_{\text{DVP}} = 19$ is **sub-threshold** (threshold at $p > 26$), the system's vacuum topology inherits sub-threshold damping from the DVP lattice, producing smooth rather than resonant UQFF coupling profiles. The DVP framework traces to PAPER_877 proto-nuclear shell formation: the DPM proportion pair ($f'_{\text{UA}} + f_{\text{SCm}} = 1$) constrains which primes are accessible at each atomic number.

§B.3 Buoyancy Saturation Harmonics (BSH)

The BSH saturation timescale for this sector is **10⁹ yr** (disk settling timescale):

$$\mathcal{F}_{\text{BSH}} = \sum_{j=1}^{26} \frac{1}{j} \cdot f_{U_b} \cdot (1 - e^{-[SSq] \cdot m/M_{\odot}}) \cdot \cos\left(\frac{2\pi j}{26}\right)$$

The tanh saturation envelope prevents unphysical divergence:

$$\mathcal{F}_{\text{BSH,sat}} = \mathcal{F}_{\text{BSH}} \cdot \left(1 - \tanh\left(\frac{t - t_{\text{sat}}}{\tau_{\text{BSH}}}\right)\right)$$

connecting to the PAPER_877 Stage 5 buoyancy seed $U_{b,\text{seed}} = 0.1 \cdot (\hbar c/r^2) \cdot f_{\text{SCm}}$ which initializes the harmonic series at cosmogenesis.

§B.4 Production-Scale Consistency

Framework	Canonical Value	This Paper	Status
VDS ratio	$\rho_{\text{SCm}}/\rho_{\text{UA}} = 1.894$	Local sub-ratio = 0.150	✓ Threshold-consistent
DVP prime	$p_k \in \{2,3,\dots,113\}$	$p_{\text{DVP}} = 19$	✓ Sub-threshold
BSH layers	26 harmonic terms	$j = 1 \dots 26,$ $\cos(2\pi j/26)$	✓ Full 26D projection
κ decay	$5.0 \times 10^{-4} \text{ day}^{-1}$	Applied in VDS exponential	✓ Canonical
[SSq]	0.57	Applied in BSH saturation	✓ Canonical
