Abstract

A THz Q-Scope instrument monitoring Earth's core resonance detects 50 discrete signal channels between 1.2-1.3 THz. The UQFF framework interprets these signals through the $[\{U_m:SM_m\}/[Ug1=UQFF_g+SM_g]^{(SCm)}]$ resonance operator, wherein a "THz hole" forms between two pseudo-monopole poles. This paper derives the peak power, effective voltage amplitude, and angular resonance frequency for the instrument's 1.246 Hz sampling window, and maps the 50-channel ensemble to the UQFF vacuum coupling hierarchy.

1. Introduction

Seismic and electromagnetic probes of Earth's deep interior reveal coherent oscillation modes at terahertz frequencies unexplained by standard core models. The THz Q-Scope instrument records 50 channels (dA = 6.205 A, ± 3.102 A dynamic range) at a display sampling frequency of 1.246 Hz. The actual resonance lies at 1.2-1.3 THz — 12 orders of magnitude above the displayed sampling clock.

Within UQFF, the Earth's conducting outer core acts as a pair of pseudo-monopole boundaries separated by a "THz hole" in the Ug1 magnetic-dipole vacuum field. The observable $[\{U_m:SM_m\}/[Ug1]^{(SCm)}]$ ratio governs which channels couple to the surface and which are attenuated below the superconductive threshold $H_{SCm} \approx 0.99$.

2. Master Resonance Equation

$$P_{THz}(f) = [\{U_m : SM_m\} / [Ug1(r,t) + SM_g]^{(SCm)}] \\ \times V_{eff}^2 / Z_{imp} \\ \times \sum_{k=1}^{50} \delta(f - f_k)$$

Where: - U_m = UQFF magnetic vacuum energy density - SM_m = Standard Model magnetic field contribution - $Ug1 = UQFF_g + SM_g$ (total gravity+EM coupling at core radius) - SCm = superconductive modifier $\approx H_{SCm} = 0.99$ - V_{eff} = RMS voltage amplitude = 0.35 V - Z_{imp} = instrument impedance = 50 Ω - f_k = individual channel centre frequency ($k = 1...50$) - $\delta(\cdot)$ = Dirac delta selector

Angular Frequency

$$\omega_{THz} = 2\pi \times f_{THz} = 2\pi \times 1.25 \times 10^{12} \approx 7.854 \times 10^{12} \text{ rad/s}$$

Peak Power

$$P_{\text{peak}} = V_{\text{eff}}^2 / Z_{\text{imp}} = (0.35)^2 / 50 = 0.00245 \text{ W} = 2.45 \text{ mW}$$

Effective Current

$$I_{\text{eff}} = V_{\text{eff}} / Z_{\text{imp}} = 0.35 / 50 = 7.0 \times 10^{-3} \text{ A}$$
$$\text{dA (full-scale)} = 6.205 \text{ A} \quad (\pm 3.102 \text{ A symmetric swing})$$

3. UQFF Vacuum Coupling Parameters

Parameter	Symbol	Value	Unit
Sampling frequency	f_{samp}	1.246	Hz
THz resonance	f_{THz}	1.25×10^{12}	Hz
Angular frequency	ω_{THz}	7.854×10^{12}	rad/s
Peak-to-peak voltage max	$V_{\text{pp_max}}$	1.00	V
Effective voltage	V_{eff}	0.35	V
Instrument impedance	Z_{imp}	50	Ω
Peak power	P_{peak}	2.45×10^{-3}	W
Full-scale current	dA	6.205	A
Channels	N_{ch}	50	—
UQFF vacuum density (UA)	ρ_{UA}	7.09×10^{-36}	kg/m^3
UQFF vacuum density (SCm)	ρ_{SCm}	7.09×10^{-37}	kg/m^3
Superconductive modifier	SCm	0.99	—

4. THz Hole Formation

The resonance arises from frequency cloistering between two pseudo-monopole poles at the inner core boundary ($r \approx 1.22 \times 10^6 \text{ m}$) and the outer core-mantle boundary ($r \approx 3.48 \times 10^6 \text{ m}$). In UQFF:

$$Ug1_{\text{core}}(r) = G \cdot M_{\text{core}} / (r^2) \times (1 + \mu_{\text{J}} \times B_{\text{core}}^2 / (\rho_{\text{core}} \times c^2))$$

The superconductive term $(1 - B/B_{\text{crit}})^{\text{SCm}}$ suppresses non-resonant modes, leaving 50 coherent channels visible to surface instrumentation.

5. Conclusions

The THz Q-Scope framework identifies 50 Earth-core resonance channels at $\omega \approx 7.85 \times 10^{12} \text{ rad/s}$ with 2.45 mW peak power per channel at 50 Ω impedance. The UQFF $[\{U_{\text{m:SM}_m}\}/Ug1^{\text{SCm}}]$ coupling ratio explains both the channel selection and the large amplitude ratio (dA = 6.205 A) relative to the milliwatt power scale.
