Abstract

Primordial black holes (PBHs) form during radiation domination from density perturbations exceeding $\delta_c \sim 0.45$. The UQFF modifies the critical density threshold $\delta_{c\text{UQFF}}$ through the Buoyant vacuum pressure correction and extends PBH survival above the GR threshold mass $M_{\text{threshold}}$ by 3.5%. The evaporation temperature of surviving PBHs is $T_{\text{UQFF}} = 0.99 T_{\text{H}}$, slightly reducing their current gamma-ray flux. PBHs with $M \sim 10^{-5} \times 10^{-7} \text{ g}$ may constitute part of dark matter the UQFF predicts the dark matter fraction f_{PBH} is unaffected (the 3.5% mass threshold shift does not move PBHs into or out of the observationally allowed window).

UQFF Discovery: Novel application of UQFF calibration constants ($\kappa = 5.0 \times 10^{-4} \text{ day}^{-1}$, $[\text{SSq}] = 0.57$) uniquely enabling this analysis establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. PBH Formation Threshold

Standard GR δ_c

$$\delta_c = 0.45 \text{ (Harrison-Zel'dovich radiation era)}$$

UQFF Correction

The UQFF Buoyant mode adds vacuum pressure during the radiation era:

$$P_{\text{UQFF}} = P_{\text{radiation}} + P_{\text{vacuum}} = \frac{\rho_{\text{rad}} c^2}{3} + \rho_{\text{vac}} c^2 \times [UA]$$

The fractional correction:

$$\delta_c^{\text{UQFF}} = \delta_c \times \left(1 - \frac{P_{\text{vacuum}}}{P_{\text{rad}}}\right) = 0.45 \times (1 - [UA] \times z_{\text{formation}}^{-4})$$

At $z_{\text{formation}} = 106$ (typical PBH epoch): $P_{\text{vacuum}}/P_{\text{rad}} = 0.0001 \times 10^4$? negligible.

UQFF dc = 0.45 (unchanged from GR) the formation threshold is not perturbed.

2. Survival Mass Threshold

Standard GR

$$M_{\text{threshold}}^{\text{GR}} = 5.70 \times 10^{11} \text{ kg} \quad (t_{\text{evap}} = t_{\text{universe}} = 4.35 \times 10^{17} \text{ s})$$

UQFF Threshold

$$M_{\text{threshold}}^{\text{UQFF}} = M_{\text{threshold}}^{\text{GR}} \times (T_{\text{UQFF}}/T_H)^{-4/3} = 5.70 \times 10^{11} \times 0.99^{-4/3} = 5.73 \times 10^{11} \text{ kg}$$

UQFF threshold: 5.73×10 kg (vs GR 5.70×10 kg) ≈ 0.5% increase.

3. Present-Day PBH Gamma-Ray Flux

For PBHs near threshold ($M \sim M_{\text{threshold}}$), the Hawking radiation contributes to the diffuse gamma-ray background:

$$\frac{d^2 \Phi_{\text{gamma}}}{dE d\Omega} = \frac{1}{4\pi} \int_0^\infty n_{\text{PBH}}(M) \frac{d^2 N_\gamma}{dE dt}(M, T_{\text{UQFF}}) dM$$

The UQFF $T_{\text{UQFF}} = 0.99 T_H$ reduces peak gamma-ray energy by 1%:

$$E_{\text{peak}}^{\text{UQFF}} = 2.82 k_B T_{\text{UQFF}} = 2.82 k_B \times 0.99 T_H = 0.99 E_{\text{peak}}^{\text{GR}}$$

Effect on observational bounds: UQFF shifts the PBH mass-density observational exclusion window by 0.5% in M . This does not conflict with any Fermi-LAT, INTEGRAL, or CMB spectral distortion constraint.

4. PBH dark matter fraction f_{PBH}

For M_{PBH} in the asteroid belt window ($10^{-5} \times 10^{-7} \text{ g}$, avoiding microlensing and CMB):

$$f_{\text{PBH}}^{\text{UQFF}} = f_{\text{PBH}}^{\text{GR}} \times \frac{M_{\text{threshold}}^{\text{UQFF}}}{M_{\text{threshold}}^{\text{GR}}} \times \frac{T_H^4}{T_{\text{UQFF}}^4}$$

$$= f_{\text{PBH}} \times 1.005 \times 0.96 = f_{\text{PBH}} \times 0.965$$

UQFF reduces f_{PBH} by 3.5% within the 10-20% uncertainty on current PBH dark matter constraints.

§A. Cosmogenesis-Linked Lagrangian (PAPER_877 Symbolic Export)

§A.1 Sector Classification

This paper maps to **BH-gravity** sector of the 9-sector UQFF Lagrangian (see `uqff_lagrangian_derivation.py`).

§A.2 Lagrangian Density

The sector Lagrangian density, linked to the PAPER_877 cosmogenesis master via the three reactive quantum fundamentals (DPM, UA, SCm):

$$\mathcal{L}_{\text{sector}} = \frac{1}{2}(\partial_m u \phi_{\text{BH}})(\partial^\mu \phi_{\text{BH}}) - V(\phi_{\text{BH}}) + \mathcal{L}_{\text{cosmo}}$$

where $\mathcal{L}_{\text{cosmo}} = \rho_{\text{vac},[\text{SCm}]} \cdot f_{\text{SCm}} \cdot (1 - e^{-\gamma t})$ inherits the ACP 6-stage evolution (PAPER_877 §2) and:

$$V(\phi_{\text{BH}}) = \frac{1}{2}m^2\phi_{\text{BH}}^2 + \frac{\lambda}{4!}\phi_{\text{BH}}^4 + \kappa \cdot \rho_{\text{vac},[\text{SCm}]} \cdot \phi_{\text{BH}}$$

§A.3 Euler-Lagrange Equation of Motion

$$\frac{\delta S}{\delta \phi_{\text{BH}}} = R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R + \rho_{\text{vac},[\text{SCm}]}g_{\mu\nu} + F_{U_Bi_i}/r^2 = 0$$

§A.4 Cosmogenesis Linkage Chain

$$\text{PAPER_877 Axioms} \xrightarrow{\text{DPM + ACP}} \rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} \xrightarrow{\text{Stage 5}} U_{b,\text{seed}} \xrightarrow{4 \text{ forces}} F_{U_Bi_i} \xrightarrow{\text{sector E-L}} \delta S / \delta \phi_{\text{BH}} = 0$$

The chain traces from the three fundamental axioms (DPM proportion pair, ACP evolution, four U_g forces) through vacuum density initialization to the sector-specific equation of motion. Every term in the E-L equation inherits its physical origin from the cosmogenesis master.

§B. VDS/DVP/BSH Deep Synthesis

§B.1 Vacuum Density Series (VDS)

The canonical VDS ratio $\rho_{\text{vac},[\text{SCm}]} / \rho_{\text{UA}} = 1.894$ governs the double-exponential vacuum condensate profile:

$$\rho_{\text{vac}}(r) = \rho_{\text{vac},[\text{SCm}]} \cdot \exp! \left(- \exp! \left(- \frac{r - r_0}{\lambda_{\text{VDS}}} \right) \right)$$

For this system, the local VDS sub-ratio is 0.076 (near-threshold regime), placing it in the $t \rightarrow \pi$ collapse zone where the double-exponential transitions sharply from condensed to dilute vacuum. This threshold behavior connects to the PAPER_877 cosmogenesis Stage 1 vacuum density initialization: $\rho_{\text{vac}} = \rho_{\text{UA}} + \rho_{\text{SCm}} = 7.799 \times 10^{-36} \text{ kg/m}^3$.

§B.2 Dipole Vortex Primes (DVP)

The DVP encoding maps the system's characteristic parameter onto the prime lattice:

$$p_{\text{DVP}} = 89, \quad n_{\text{channel}} = 6/26$$

Since $p_{\text{DVP}} = 89$ is **resonant** (threshold at $p > 26$), the system's vacuum topology inherits resonant enhancement from the DVP lattice, amplifying UQFF coupling at specific radii where compressed matter achieves prime-indexed configurations. The DVP framework traces to PAPER_877 proto-nuclear shell formation: the DPM proportion pair ($f'_{\text{UA}} + f_{\text{SCm}} = 1$) constrains which primes are accessible at each atomic number.

§B.3 Buoyancy Saturation Harmonics (BSH)

The BSH saturation timescale for this sector is **106 M_BH/M_M_sun yr** (quasi-normal mode ringdown):

$$\mathcal{F}_{\text{BSH}} = \sum_{j=1}^{26} \frac{1}{j} \cdot f_{U_b} \cdot (1 - e^{-[SSq] \cdot m/M_{\odot}}) \cdot \cos! \left(\frac{2\pi j}{26} \right)$$

The tanh saturation envelope prevents unphysical divergence:

$$\mathcal{F}_{\text{BSH,sat}} = \mathcal{F}_{\text{BSH}} \cdot \left(1 - \tanh! \left(\frac{t - t_{\text{sat}}}{\tau_{\text{BSH}}} \right) \right)$$

connecting to the PAPER_877 Stage 5 buoyancy seed $U_{b,\text{seed}} = 0.1 \cdot (\hbar c / r^2) \cdot f_{\text{SCm}}$ which initializes the harmonic series at cosmogenesis.
