

PAPER_430 — SGR 0501+4516 Magnetar: First Complete Per-System MUGE Derivation

Source: grok_share_68eb34022.txt — Document 2: “Master Universal Gravity Equation_Magnetar_03May2025.docx” (lines 84–880; full analysis + C++ encoding of SGR 0501+4516 MUGE) **Session:** 119 **CP4 Class:** SGR0501_4516_MagnetarPerSystemMUGECalculator (#85)

1. Overview

PAPER_430 presents the first complete per-system Master Universal Gravity Equation (MUGE) for **SGR 0501+4516**, a magnetar distinct from SGR 1745-2900 (previously modelled in PAPER_342/343). SGR 0501+4516 is observed ~80 arcminutes from supernova remnant HB9, with magnetic field evolution $B(t) = 10^{10} \exp(-t/\tau_B)$ T and rotation rate $\Omega(t) = (2\pi/P_0) \exp(-t/\tau_\Omega)$, where this paper derives the **complete 10-term g_Magnetar(r,t)** incorporating all UQFF force channels.

Novel claim (Q1): First complete UQFF-MUGE for SGR 0501+4516, combining all 10 gravitational channels into a single calibrated expression evaluated at $t = 5000$ yr, yielding $g_{\text{Magnetar}} \approx 4.474 \times 10^{12} \text{ m/s}^2$.

Physical significance: SGR 0501+4516’s motion away from HB9 challenges standard supernova formation; the UQFF time-reversal component f_{TRZ} and Universal Aether (UA) coupling provide a non-standard magnetic field enhancement mechanism consistent with this anomaly.

2. System Parameters

Parameter	Symbol	Value	Source
Magnetar mass	M	$1.4 M_\odot = 2.785 \times 10^{30} \text{ kg}$	Compact stellar remnant standard
Radius	r	$20 \times 10^3 \text{ m}$ (20 km)	Neutron star typical
Initial B field	B_0	10^{10} T	SGR 0501+4516 observation
B decay timescale	τ_B	4000 yr $= 1.262 \times 10^{11} \text{ s}$	Hubble dataset
Critical B field	B_{crit}	10^{11} T	Type-II SC threshold
Initial period	P_0	5 s	Standard magnetar period
Ω decay timescale	τ_Ω	10,000 yr $= 3.156 \times 10^{11} \text{ s}$	Fermilab simulation
Hubble constant	H_0	$2.184 \times 10^{-18} \text{ s}^{-1}$	Planck CMB
Time-reversal factor	f_{TRZ}	0.1	UQFF calibration
EM scaling	s_{EM}	10^{-12}	Macroscopic approximation
UA vacuum density	ρ_{UA}	$7.09 \times 10^{-36} \text{ J/m}^3$	UQFF canonical

Parameter	Symbol	Value	Source
SCm vacuum density	ρ_{SCm}	$7.09 \times 10^{-37} \text{ J/m}^3$	UQFF canonical

3. Time-Dependent Functions

Magnetic field decay:

$$B(t) = B_0 e^{-t/\tau_B} = 10^{10} e^{-t/1.262 \times 10^{11}} \quad [\text{T}]$$

Rotation rate decay:

$$\Omega(t) = \frac{2\pi}{P_0} e^{-t/\tau_\Omega} \quad [\text{rad/s}]$$

Ω derivative (spin-down):

$$\frac{d\Omega}{dt}(t) = -\frac{2\pi}{P_0 \tau_\Omega} e^{-t/\tau_\Omega} \quad [\text{rad/s}^2]$$

At $t = 5,000 \text{ yr} = 1.578 \times 10^{11} \text{ s}$: - $B(5000 \text{ yr}) = 10^{10} \cdot e^{-1.578/1.262} \approx 0.0829 \times 10^{10} \text{ T}$ - $B/B_{\text{crit}} = 8.29 \times 10^{-3} \Rightarrow 1 - B/B_{\text{crit}} \approx 0.9917$

4. Complete 10-Term MUGE

$$g_{\text{Magnetar}}(r, t) = \sum_{k=1}^{10} T_k$$

Term 1 — Base Newtonian gravity with cosmic expansion and magnetic SC correction

$$T_1 = \frac{GM}{r^2} \cdot (1 + H_0 t) \cdot \left(1 - \frac{B(t)}{B_{\text{crit}}}\right)$$

At $t = 5000 \text{ yr}$:

$$T_1 = \frac{6.674 \times 10^{-11} \times 2.785 \times 10^{30}}{(2 \times 10^4)^2} \times 1.0000003 \times 0.9917 \approx 4.607 \times 10^{11} \text{ m/s}^2$$

Term 2 — UQFF Ug1 + Ug4 co-sum with f_TRZ correction

$$T_2 = (U_{g1} + U_{g4}) \cdot (1 + f_{\text{TRZ}})$$

Where: - $U_{g1} = GM/r^2 = 4.645 \times 10^{11} \text{ m/s}^2$ - $U_{g4} = U_{g1} \cdot (1 - B(t)/B_{\text{crit}}) \approx 4.512 \times 10^{11} \text{ m/s}^2$

$$T_2 = (4.645 \times 10^{11} + 4.512 \times 10^{11}) \times 1.1 \approx 1.007 \times 10^{12} \text{ m/s}^2$$

Term 3 — Cosmological constant

$$T_3 = \frac{\Lambda c^2}{3} = \frac{1.1 \times 10^{-52} \times (3 \times 10^8)^2}{3} \approx 3.3 \times 10^{-36} \text{ m/s}^2 \quad [\text{negligible}]$$

Term 4 — Quantum uncertainty (Heisenberg correction)

$$T_4 = \frac{\hbar}{\Delta x \cdot \Delta p} \cdot \int \psi^\dagger \hat{H} \psi dV \cdot \frac{2\pi}{t_H} \approx 2.176 \times 10^{-18} \text{ m/s}^2 \quad [\text{negligible for macroscopic}]$$

Term 5 — Electromagnetic force (scaled macroscopic UA correction)

$$T_5 = \frac{q(v \times B(t))}{m_p} \cdot \left(1 + \frac{\rho_{\text{UA}}}{\rho_{\text{SCm}}}\right) \cdot s_{\text{EM}}$$

Where $\rho_{\text{UA}}/\rho_{\text{SCm}} = 10$:

$$T_5 = \frac{1.602 \times 10^{-19} \times 10^6 \times B(5000 \text{ yr})}{1.673 \times 10^{-27}} \times 11 \times 10^{-12} \approx 3.018 \times 10^{12} \text{ m/s}^2$$

Term 6 — Fluid/internal forces

$$T_6 \approx 0 \quad [\text{internal forces cancel for gravity}]$$

Term 7 — Oscillatory radiation mode

$$T_7 \approx 0 \quad [\text{subdominant at stellar radius}]$$

Term 8 — Dark matter perturbation

$$T_8 = (M + M_{\text{DM}}) \cdot \frac{\delta\rho/\rho + 3GM/r^3}{r^2}$$

$$T_8 \approx 2.135 \times 10^{41} \text{ kg m}^{-1} \quad [\text{mass-scale quantity; not additive to acceleration}]$$

Term 9 — Gravitational wave spin-down

$$T_9 = \frac{GM^2}{c^4 r} \cdot \left(\frac{d\Omega}{dt}\right)^2$$

$$T_9 \approx 9.297 \times 10^{-10} \text{ m/s}^2 \quad [\text{negligible}]$$

Term 10 — UQFF f_TRZ time-reversal residual

$$T_{10} = f_{\text{TRZ}} \cdot T_1 \quad [\text{already included in } T_2]$$

5. Total Computed Value

$$g_{\text{Magnetar}}(r = 20 \text{ km}, t = 5000 \text{ yr}) \approx 4.474 \times 10^{12} \text{ m/s}^2$$

Term dominance:

Term	Magnitude (m/s ²)	Fraction
T_1 (base + H_0 + B/B_c)	4.607×10^{11}	10.3%
T_2 (UQFF Ug + f_{TRZ})	1.007×10^{12}	22.5%
T_5 (EM + UA)	3.018×10^{12}	67.4%
All others	$< 10^{-9}$	negligible
Total	4.474×10^{12}	100%

6. Comparison to Standard Model

The standard model for magnetar surface gravity is:

$$g_{\text{SM}} = \frac{GM}{r^2} \approx 4.645 \times 10^{11} \text{ m/s}^2$$

UQFF enhancement factor: $g_{\text{UQFF}}/g_{\text{SM}} \approx 9.63\times$ — the EM term with UA/SCm ratio provides the dominant amplification. The standard model omits: - UA/SCm vacuum density ratio coupling ($\rho_{\text{UA}}/\rho_{\text{SCm}} = 10$) - f_{TRZ} time-reversal Ug correction (+10%) - Magnetic field superconductivity correction to base gravity

7. Testable Predictions

Q5 Prediction 1: The EM-dominant term predicts that as $B(t)$ decays over 10,000 yr, g_{Magnetar} should decrease by $\sim \Delta g/g \approx 0.064$ (~6.4%) — measurable via future X-ray timing or FRB periodicity studies (Fermilab, CHIME).

Q5 Prediction 2: The f_{TRZ} correction implies a 10% gravitational asymmetry between infall and outward trajectories from the magnetar surface, potentially detectable as a timing asymmetry in burst arrival rates.

Q5 Prediction 3: UQFF predicts $g_{\text{Magnetar}}(t = 0) \approx 5.523 \times 10^{12} \text{ m/s}^2$ — 23% higher than current epoch — suggesting magnetic burst intensity should have been observably stronger at formation (t=0).

8. Implementation in CP4

```
class SGR0501_4516_MagnetarPerSystemMUGECalculator:
    """PAPER_430 - First complete per-system MUGE for SGR 0501+4516"""
```

```

def compute(self, t_yr: float = 5000.0) -> dict:
    import math
