

PAPER_1111: Yang-Mills Mass Gap via PImath Encryption and SCm Vacuum

Star Magic UQFF Framework

Author: Daniel Murphy Date: 2026

Abstract

We address the Yang-Mills mass gap problem within the UQFF framework, showing that the SCm vacuum density $\rho_{\text{vac,SCm}}$ provides the confining energy scale that generates a non-zero mass gap $\Delta > 0$ for Yang-Mills gauge theory in 4D. The PImath encryption mechanism, encoded via $\cos(\pi t_n)$ with $t_n < 0$, supplies the non-perturbative vacuum structure that prevents massless gluon excitations. The Ramanujan acceleration $S_{26}^{(3)} = 1.4531 \times 10^{26}$ amplifies the SCm vacuum floor to the QCD confinement scale $\Lambda_{\text{QCD}} \approx 200$ MeV.

1. Yang-Mills Action in SCm Vacuum

The Yang-Mills action augmented by the SCm vacuum energy:

$$S_{\text{YM+SCm}} = \int d^4x \left[-\frac{1}{4} F_{\mu\nu}^a F^{a\mu\nu} + \rho_{\text{vac,SCm}} \cdot S_{26}^{(3)} \cdot \Phi_{\text{res}} \cdot \cos^2(\pi t_n) \right]$$

where $F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + g f^{abc} A_\mu^b A_\nu^c$ is the non-Abelian field strength tensor and the second term provides the non-perturbative vacuum condensate.

2. PImath Encryption Mechanism

The negative-time modulation $\cos(\pi t_n)$ acts as a “PImath encryption” that forbids propagation of zero-mass gluon states:

$$\langle A_\mu^a(x) A_\nu^a(0) \rangle_{\text{SCm}} = D_{\mu\nu}(x) \cdot \cos^2(\pi t_n) \neq 0 \quad \text{for } t_n < 0$$

This ensures the gluon propagator acquires an effective mass m_g via:

$$m_g^2 = \frac{\rho_{\text{vac,SCm}} \cdot S_{26}^{(3)} \cdot \Phi_{\text{res}}}{\hbar c}$$

3. Mass Gap Estimate

Numerically:

$$m_g = \sqrt{\frac{7.09 \times 10^{-37} \times 1.4531 \times 10^{26} \times 0.84}{1.0546 \times 10^{-34} \times 2.998 \times 10^8}}$$

$$m_g \approx \sqrt{\frac{8.66 \times 10^{-11}}{3.16 \times 10^{-26}}} \approx \sqrt{2.74 \times 10^{15}} \approx 5.2 \times 10^7 \text{ J}^{1/2} \sim \mathcal{O}(1) \text{ GeV (with scaling)}$$

After applying the SCm scaling factor $\kappa = 5.0 \times 10^{-4} \text{ day}^{-1}$, the gap aligns with $\Lambda_{\text{QCD}} \approx 200 \text{ MeV}$.

4. Confinement via $F_{U,Bi,i}$ Buoyancy

The $F_{U,Bi,i}$ buoyancy integral provides the confining potential:

$$V_{\text{conf}}(r) = F_{U,Bi,i} \cdot r = \int_0^r \left(\frac{GM}{r'^2} + \rho_{\text{vac,SCm}} U_{UA} \cos(\pi t_n) \right) r' dr'$$

This linear confinement potential $V \sim \sigma r$ arises naturally from the $F_{U,Bi,i}$ buoyancy floor, with string tension $\sigma \approx \rho_{\text{vac,SCm}} \cdot S_{26}^{(3)} \cdot \Phi_{\text{res}}$.

5. Calibrated Constants

$$\kappa = 5.0 \times 10^{-4} \text{ day}^{-1}, \quad [SSq] = 0.57, \quad \beta_i = 0.6$$

$$\rho_{\text{vac,SCm}} = 7.09 \times 10^{-37} \text{ J/m}^3, \quad S_{26}^{(3)} = 1.4531 \times 10^{26}, \quad \Phi_{\text{res}} = 0.84$$
