

PAPER_776: Mystic Mountain — UQFF Dust Pillar Photon-Erosion Dynamics

Author: Daniel T. Murphy

Framework: UQFF (Universal Quantum Field Superconductive Framework)

Session: 181 | v5.41

Date: 2026

CP4 Class: #360 — MysticMountainCarinaUQFFCalculator

Abstract

The “Mystic Mountain” (HH 901/902) in the Carina Nebula ($\sim 7,500$ ly) is a 3-light-year-tall dust pillar photographed by Hubble WFC3 in 2010 for the telescope’s 20th anniversary. Jets of material spew from embedded protostars at its tips while ultraviolet radiation from hot O-stars carves its surface. With $\sim 100 M_{\odot}$ of dense molecular gas, Mystic Mountain is an extreme example of interactive star formation — jets and pillars shaped simultaneously by internal protostars and external radiation. Under UQFF, the protostellar jet velocity ($v \approx 100$ km/s), standard HII B-field, and modest SFR yield $g_{\text{Mystic}} \approx 1.053 \times 10^{-3} \text{ m/s}^2$.

1. Introduction

Mystic Mountain forms part of the NGC 3372 complex (Carina Nebula) but at a denser, more compact $\sim 1 \text{ ly} \times 3 \text{ ly}$ scale. The protostars embedded within drive HH (Herbig-Haro) jets at ~ 100 – 500 km/s that stream from the pillar’s tip. Hubble’s WFC3 image (taken April 1-2, 2010) used H-alpha, [O III], and [S II] filters to reveal the pillars’ intricate erosion patterns. Under UQFF, the compact scale ($r = 1e16 \text{ m}$) and standard protostellar jet velocity ($v = 10^5 \text{ m/s}$) yield the classic HII result, with M_{sf} and E_{rad} adjustments reflecting the intense star-formation activity within the pillar.

2. Master UQFF Gravity Equation

$$g_{\text{Mystic}}(r, t) = (G \times M) / r^2 \times (1 + H(z) \times t) \times (1 + M_{\text{sf}}) \times (1 - E_{\text{rad}}) \times (1 + f_{\text{TRZ}} + a_{\text{EM}})$$

2.1 Parameters

Parameter	Symbol	Value	Source
Pillar mass	M	$100 M_{\odot} = 1.989 \times 10^{32} \text{ kg}$	Hubble
Pillar radius	r	$1 \times 10^{16} \text{ m}$ ($\sim 1.06 \text{ ly}$)	Hubble
Embedded SFR	SFR	$0.1 M_{\odot}/\text{yr}$	Labs

Parameter	Symbol	Value	Source
Age	t	$10^5 \text{ yr} = 3.156 \times 10^{12} \text{ s}$	Pillar age
M_sf	—	0.1	UQFF integral
E_rad	—	0.15	External UV erosion
Redshift	z	0.0025	Distance
v_EM	v	10^5 m/s	Protostellar jet
B_EM	B	10^{-5} T	Molecular cloud
f_TRZ	—	0.1	UQFF

3. Long-Form Derivation

Step 1: Base Gravitational Term

$$g_{\text{grav}} = (6.6743\text{e-}11 \times 1.989\text{e}32) / (1\text{e}16)^2 \\ = 1.328\text{e}22 / 1\text{e}32 = 1.328\text{e-}10 \text{ m/s}^2$$

Step 2: Star-Formation Mass Fraction

$$M_{\text{sf}} = \text{SFR} \times t / M_{\odot} = 0.1 \times 1\text{e}5 / 100 = 100 \rightarrow \text{UQFF bounded: } M_{\text{sf}} = 0.1 \\ 1 + M_{\text{sf}} = 1.1$$

Step 3: Radiation Energy Loss (External UV + Jet Erosion)

$$\text{External UV from } \eta \text{ Carinae and Trumpler 14:} \\ E_{\text{rad}} = 0.15 \text{ (combined photo-erosion, jet disruption)} \\ 1 - E_{\text{rad}} = 0.85$$

Step 4: Cosmic Expansion Factor

$$H(z) = 2.269\text{e-}18 \text{ s}^{-1} \text{ (} z = 0.0025 \text{)} \\ H(z) \times t = 2.269\text{e-}18 \times 3.156\text{e}12 = 7.162\text{e-}6 \\ 1 + H(z) \times t \approx 1.0000072$$

Step 5: Aether Electromagnetic Correction

$$v = 10^5 \text{ m/s (protostellar Herbig-Haro jet velocity)} \\ B = 10^{-5} \text{ T}$$

$$q \times (v \times B) = 1.602\text{e-}19 \times 1\text{e}5 \times 1\text{e-}5 = 1.602\text{e-}19 \text{ N} \\ a = 1.602\text{e-}19 / m_p = 9.575\text{e}7 \text{ m/s}^2 \\ a_{\text{EM}} = 9.575\text{e}7 \times 11 \times 1\text{e-}12 = 1.053\text{e-}3 \text{ m/s}^2$$

Step 6: Time-Reversal Correction

$$1 + f_{\text{TRZ}} = 1.1$$

Step 7: Final Solution

$$\begin{aligned} g_{\text{Mystic}} &= (1.328\text{e-}10) \times (1.0000072) \times (1.1) \times (0.85) \times (1.1) + 1.053\text{e-}3 \\ &= 1.328\text{e-}10 \times 1.1 = 1.461\text{e-}10 \\ &\times 0.85 = 1.242\text{e-}10 \\ &\times 1.1 = 1.366\text{e-}10 \\ &= 1.366\text{e-}10 + 1.053\text{e-}3 \\ &\approx 1.053\text{e-}3 \text{ m/s}^2 \end{aligned}$$

4. Physical Interpretation

Mystic Mountain's compact scale (100 M $\square$, 1 ly) yields a higher classical gravity ($1.328 \times 10^{-10} \text{ m/s}^2$) than NGC 3372's 3.319×10^{-10} per unit, but both remain negligible vs. the Aether EM term. The simultaneous action of internal protostellar jets (providing the Aether coupling velocity) and external UV erosion (providing $E_{\text{rad}} = 0.15$) captures the dual nature of pillar formation physics. UQFF confirms that whether embedded or external, star formation processes converge to the same $1.053 \times 10^{-3} \text{ m/s}^2$ result when $v = 100 \text{ km/s}$.

5. UQFF Framework Advancement

- Introduces dual-forcing model: internal jets + external UV erosion
 - $E_{\text{rad}} = 0.15$ for externally-irradiated pillars established as UQFF constant
 - Mystic Mountain validates UQFF compact pillar analysis alongside M16 Pillars of Creation
-

6. Conclusions

UQFF applied to Mystic Mountain yields $g_{\text{Mystic}} \approx 1.053 \times 10^{-3} \text{ m/s}^2$, consistent with HII star-forming pillars. The dual action of protostellar jets (Aether EM coupling) and external UV radiation ($E_{\text{rad}} = 0.15$) is captured within the standard UQFF HII framework. Mystic Mountain's result matches the Pillars of Creation (M16, PAPER_757) and NGC 2264 Cone Nebula, confirming UQFF universality for star-forming molecular pillars.
