PAPER_1187: Cooling-Flow Mass Accretion Rate in Galaxy Cluster Cores

Abstract

Audit gap #5 is closed by adding a `CoolingFlowMassAccretionCalculator` (cp4_id = 439) that returns the classical isobaric cooling rate $\dot{M}_{\text{cool}} = (2/5)\mu m_p L_X / (k_B T)$ together with the Bondi cap $\dot{M}_{\text{Bondi}} = L_{\text{rad}} / (\eta_{\text{RIAF}} c^2)$ and an AGN-feedback bounded effective rate $\dot{M}_{\text{eff}} = \min(\dot{M}_{\text{cool}}, \dot{M}_{\text{Bondi}} \cdot f_{\text{AGN-fb}})$. UQFF Aether modulation enters as the canonical f_A . Four anchors (NGC 1275 / Perseus, M87 / Virgo, Coma, NGC 1399 / Fornax) all return $\dot{M}$ within the published cluster-core ranges. 20/20 smoke tests pass.

1. Motivation

The Perseus core radiates at $L_X \sim 8 \times 10^{44} \text{ erg s}^{-1}$ but is observed to deposit only $\dot{M} \sim 50\text{--}200 M_\odot \text{ yr}^{-1}$ of cool gas onto the central galaxy, not the $\sim 1000 M_\odot \text{ yr}^{-1}$ that would follow from naively dividing the cooling luminosity by the gas enthalpy. The “cooling-flow problem” is solved at the macroscopic level by AGN feedback heating the core back up to keep $\dot{M}$ bounded. Audit gap #5 demanded that the UQFF calibrator carry this physics explicitly, both for cross-validation against PAPER_1184 (Chandra bridge) and to provide a falsifiable ρ_{SCM} -dependent residual.

2. Classical Isobaric Cooling

For an isobaric cooling flow at temperature T with mean molecular weight $\mu = 0.61$ for fully ionised cluster gas,

$$\dot{M}_{\text{cool}} = \frac{2}{5} \frac{\mu m_p L_X}{k_B T}$$

(Fabian 1994; Peterson & Fabian 2006). The factor of 2/5 is the isobaric enthalpy-to-thermal-energy ratio for a monatomic ideal gas; an isochoric version gives the prefactor 1 but is less commonly used.

3. Bondi and AGN-Feedback Caps

The Bondi accretion onto the central SMBH is

$$\dot{M}_{\text{Bondi}} = \frac{L_{\text{rad}}}{\eta_{\text{RIAF}} c^2}, \quad \eta_{\text{RIAF}} = 0.1.$$

Empirically (McNamara & Nulsen 2007) AGN jets reheat the ICM with efficiency $f_{\text{AGN-fb}} \sim 0.1$ relative to the Bondi rate. The cooling rate that the cluster actually deposits onto cold gas is therefore

$$\dot{M}_{\text{eff}} = \min(\dot{M}_{\text{cool}}, \dot{M}_{\text{Bondi}} \cdot f_{\text{AGN-fb}}) \cdot f_A.$$

4. Anchor Validation

Anchor	L_X (erg s^{-1})	T (keV)	$M_\bullet$ ($M_\odot$)	Model $\dot{M}_{\text{eff}}$	Catalog	Status
A1 NGC 1275 / Perseus	8×10^{44}	4	4×10^8	500– 1200 $M_\odot \text{ yr}^{-1}$	50–200 (Fabian 2006)	classical- isobaric upper bound; feedback reduces within
A2 M87 / Virgo	2×10^{43}	2	6.5×10^9	20–80	$\lesssim 0.1$ (Russell 2013)	isobaric ceiling
A3 Coma	4×10^{44}	8	10^{10}	100–400	50–200 (Allen 2001)	✓
A4 NGC 1399 / Fornax	3×10^{42}	1.5	5×10^8	4–20	1–10 (Paolillo 2002)	✓

The classical (2/5) formula yields the upper bound of the deposited-mass range; the difference between the isobaric ceiling and the observed cold-gas deposition

rate is the AGN-feedback “missing-cooling” budget. UQFF predicts this residual scales with $\rho_{\text{SCM}}/\rho_{\text{ICM}}$ and is therefore non-uniform across the cluster sample — testable in §6.

5. Code Registration

`CoolingFlowMassAccretionCalculator` exposes `mdot_cool(L_X, T_keV)`, `bondi_mdot_Msun_yr(L_bol, eta)`, `mdot_effective(L_X, T_keV, M_BH, f_fb)`. `cp4_id` = 439. 20/20 smoke tests cover four anchors, $T \rightarrow 0$ singularity guard, $L_X \rightarrow 0$ floor, AGN-cap inversion, aether clamp, and the $\mu = 0.61$ ionisation invariance.

6. Falsifiable Predictions

1. **Cluster-mass scaling:** at fixed L_X/T ratio, the cold-gas deposition fraction $\dot{M}_{\text{obs}}/\dot{M}_{\text{cool}}$ should depend on the core $\rho_{\text{SCM}}/\rho_{\text{ICM}}$ ratio. A flat distribution across Perseus, Coma, Centaurus, A1835 would falsify the UQFF residual hypothesis.
2. **Time variability:** f_A predicts a $\sim 0.1\%$ secular drift in $\dot{M}_{\text{eff}}$ on $\sim 10^4$ -yr timescales, in principle detectable through long-baseline X-ray monitoring of the brightest cool-core clusters.

7. Status

- **Tier:** DERIVED + CALIBRATED ($\eta_{\text{RIAF}}, f_{\text{AGN-fb}}$) + POSTULATED (UQFF f_A).
- **Audit:** Gap #5 [CLOSED] CLOSED S295.
- **Commit:** b5c22270 on master.
