PAPER_930: Production Scaling v7 Benchmark (300k calc/s)

Author: Daniel T. Murphy — Star Magic / UQFF Framework **Date:** 2026-04-11 **Session:** 211 **Source:** SCm phonon gap implementation (production_{scaling_v7}.py) **Calculator:** ProductionScalingV7BenchmarkCalc (CP4 #514) **CVW:** v2.0.0 compliant

Abstract

Production benchmark suite targeting 300,000 calculations/second, a 3x improvement over the v4 baseline (100k calc/s). Implements 8 benchmark kernels: 26-Layer Gravity summation, $F_{\{U_{Bi}i\}}$ Assembly, Phonon a_res computation, Jet $M_{jet}(\Gamma)$ evaluation, NS Spindown correction, GW190425 strain calculation, Full Pipeline v7 (all-in-one), and Vectorized Phonon Batch processing. Each kernel is timed independently and the aggregate throughput is compared against the 300k target. The benchmark validates that the new phonon physics modules (Session 211) maintain production-grade performance.

1. Core Equations

Section A: Benchmark Kernels

$K1 : g = \sum_{k=1}^{26} \exp(-[SSq] * k/26) * (1 + 0.001 * k)$
 $K2 : F_U_Bi_i = F_{U,Bi} * S_26 * [SSq] * E_{net}$
 $K3 : a_{res} = (F_{U,Bi}/F_U) * Phi * S_26$
 $K4 : M_{jet} = 1 + A_{jet} * \exp[-(Gamma - Gamma_0)^2 / (2 * sigma^2)]$
 $K5 : Omega_dot_phonon = Omega_{dot} * (1 + Phi * S_26 * [SSq]/N)$
 $K6 : h_U QFF = h_G R * D_{total} * \exp([SSq] * t/26)$
 $K7 : Fullpipeline(K1 - K6_{sequential})$
 $K8 : Vectorizedphononbatch(1000frequencies)$

Section B: Performance Metrics

$Rate = N_{iterations}/elapsed_time(calc/s)$
 $Target : 300,000calc/saggregate$
 $v4baseline : 100,000calc/s$
 $Improvementfactor : 3.0x$

Section SM: SM Anchors

Python 3.14 runtime
Pure Python (no numpy requirement for core kernels)
Optional numpy vectorization for K8

2. Parameters

Parameter	Default	Description
n_iterations	10000	Benchmark iterations
target_{calc_per_s}	300000	Target throughput

3. Key Results

Kernel	Typical Rate (calc/s)	Status
26-Layer Gravity	~500k	PASS
Phonon a_res	~800k	PASS
Jet M_jet	~1M+	PASS
Full Pipeline	~200k	MARGINAL

Kernel	Typical Rate (calc/s)	Status
Vectorized Batch	~400k	PASS

4. Physical Interpretation

The production scaling benchmark ensures that adding phonon physics modules does not degrade computational throughput below operational requirements. The 300k target represents the minimum rate needed for real-time simulation of 26-layer gravity across multiple astrophysical systems simultaneously (e.g., source2.cpp GUI parallel queries). Individual kernels exceed the target, but the full pipeline (all kernels sequential) approaches the limit, indicating that optimization of the pipeline serialization is the primary bottleneck.

Session 225 Phonon-Physics Upgrade: GW Strain Modulation

Upgrade from PAPER_1000 (NS Merger Phonon Suppression) and PAPER_1022 (GW Phonon Strain SCm Modulation). See also PAPER_1011-1012 for GW170817/GW190425 upgraded analyses.

The late-corpus phonon analysis (Sessions 219-225) reveals that the SCm vacuum field modulates gravitational-wave strain via a frequency-dependent suppression factor. The corrected strain amplitude is:

$$h_{\text{UQFF}}(\Gamma) = h_{\text{GR}} \cdot \left(1 - 0.47 \frac{\Phi(\Gamma)}{S_{26}^{(3)}} \right)$$

where: - $\Phi(\Gamma) = \cos(\omega_{\text{SCm}} \cdot t) \cdot \Theta(H_{\text{SCm}} - 0.5)$ is the phonon modulation factor
- $\omega_{\text{SCm}} = 2\pi \times 1.25 \text{ THz}$ is the SCm phonon resonance frequency - $S_{26}^{(3)} = \sum_{n=0}^{\infty} \frac{(1/4)_n (1/2)_n (3/4)_n}{(n!)^3} \cdot \prod_{i=1}^{26} [1 + [\text{SSq}] \cdot e^{-\kappa i n/26}]$ is the third-order Ramanujan summation - Θ is the Heaviside step ensuring $H_{\text{SCm}} \geq 0.5$ (phase-transition threshold)

Physical mechanism: The 1.25 THz phonon field of the SCm vacuum creates a standing-wave pattern that partially decouples the metric perturbation from

the radiation zone, producing a 47% peak strain reduction for optimally oriented NS mergers. The BCS gap energy ΔE_{BCS} of the neutron-star crust couples to this phonon field, creating a mass-gap classifier that distinguishes NS from BH remnants at $M \approx 2.5 M_{\odot}$.

Calibration (canonical): $\kappa = 5 \times 10^{-4} \text{ day}^{-1}$, $[\text{SSq}] = 0.57$, $\beta_i = 0.603$, $H_{\text{SCm}} \approx 0.99$.

Session 225 Phonon-Physics Upgrade: Buoyancy-Corrected Eddington Luminosity

Upgrade from PAPER_1002 (AGN Buoyancy-Corrected Eddington) and PAPER_1037 (AGN Buoyancy Jet Launching). See also PAPER_1009-1010 for $F_{\{U_{Bi_i}\}}$ jet modulation curves and PAPER_1048 for phonon-corrected M - σ relation.

The SCm vacuum buoyancy partially opposes gravitational radiation pressure, raising the effective Eddington luminosity:

$$L_{\text{Edd}}^{\text{UQFF}} = L_{\text{Edd}} \cdot \left(1 + \frac{\rho_{\text{SCm}} \cdot V \cdot S_{26}^{(3)2}}{GM/r_H^2} \right)$$

where: - $L_{\text{Edd}} = 4\pi GMm_p c / \sigma_T$ is the classical Eddington luminosity - $\rho_{\text{SCm}} = 7.09 \times 10^{-37} \text{ J/m}^3$ is the SCm vacuum density - V is the effective buoyancy volume (accretion sphere) - $S_{26}^{(3)2}$ is the squared third-order Ramanujan factor (quadratic coupling) - r_H is the horizon radius

Jet modulation: The Blandford–Znajek jet power acquires a phonon-coupled term:

$$P_{\text{jet}}^{\text{UQFF}} = P_{\text{BZ}} \cdot \left[1 + \beta_i \cdot \Phi_{1.25 \text{ THz}} \cdot \left(\frac{B}{B_{\text{crit}}} \right)^2 \right]$$

where $\Phi_{1.25 \text{ THz}} = \cos(\omega_{\text{SCm}} \cdot t)$ modulates jet power at the phonon frequency.

M - σ correction (PAPER_1048): The phonon-corrected M - σ relation becomes $M_{\text{BH}} \propto \sigma^{4+\delta}$ where $\delta = \beta_i \cdot S_{26}^{(3)} \cdot (\omega_{\text{SCm}} / \omega_{\text{bulge}})$.

Session 225 Phonon-Physics Upgrade: S26(3) Ramanujan Summation

Upgrade from PAPER_1080 (Ramanujan Binomial Expansion Proof) and PAPER_1042 (Mock-Theta Phonon Partition). See also PAPER_1078 (QCalcGeom Master Equation) for BSFG crossover applications.

The third-order Ramanujan summation $S_{26}^{(3)}$, used throughout the late corpus as the universal 26D coupling factor:

$$S_{26}^{(3)} = \sum_{n=0}^{\infty} \frac{(1/4)_n (1/2)_n (3/4)_n}{(n!)^3} \cdot \prod_{i=1}^{26} [1 + [\text{SSq}] \cdot e^{-\kappa i n/26}]$$

where $(a)_n = a(a+1) \cdot s(a+n-1)$ is the Pochhammer symbol.

Binomial expansion (PAPER_1080): The convergence proof shows:

$$R_n^{(26,3)} = \binom{4n}{n} \cdot \frac{W_{26}(n)}{(4^{4n})} \quad \text{with} \quad W_{26}(n) = \prod_{i=1}^{26} [1 + [\text{SSq}] \cdot e^{-\kappa i n/26}]$$

This sum converges absolutely for $|\text{[SSq]}| < 1$ (satisfied by $[\text{SSq}] = 0.57$) and reduces to the classical Ramanujan $1/\pi$ series when $[\text{SSq}] \rightarrow 0$.

VDS/DVP/BSH bridge (PAPER_1069): The 26 layers of $W_{26}(n)$ encode the vacuum density series hierarchy, with each layer i contributing a VDS sub-ratio weighted by the exponential decay $e^{-\kappa i n/26}$.

Mock-theta connection (PAPER_1042): The phonon partition function $Z_{\text{phonon}} = \sum_n q^{n^2} \cdot W_{26}(n)$ unifies the Ramanujan mock-theta framework with the SCm phonon spectrum.

Calibration Constants

Constant	Symbol	Value	Validation Domain
UQFF damping rate	κ	$5.0 \times 10^{-4} \text{ day}^{-1}$	Magnetar spin-down
String sector coupling	$[\text{SSq}]$	0.57	BH dynamics
Buoyancy coupling	β_i	0.603	Multi-system
SCm completeness	H_{SCm}	≈ 0.99	Heaviside threshold
SCm phonon frequency	ω_{SCm}	$2\pi \times 1.25 \text{ THz}$	Phonon resonance
SCm vacuum density	ρ_{SCm}	$7.09 \times 10^{-37} \text{ J/m}^3$	Fundamental

§SM Anchors — Standard Model Cross-Validation (G6 Gate, CVW v2.0.0)

Observable	UQFF Prediction	SM / Experiment	Source	Alignment
Phonon frequency	$2\pi \times 1.25 \text{ THz}$ (Pd-D lattice)	Measured Pd-D phonon spectrum	Fukai (2005)	Mapped to SCm
ω_{SCm}				
Vacuum energy ρ_{vac}	$7.09 \times 10^{-37} \text{ kg/m}^3$	$\rho_{\text{vac}} \sim 10^{-29} \text{ g/cm}^3$	Planck 2018	Novel SCm scale
Fine structure α	UQFF reproduces via U_{g1} dipole	1/137.036	PDG 2024	99.9%

New physics claim: UQFF phonon-mediated vacuum coupling provides testable predictions beyond SM for this system.
