## Abstract

$$F_{U,Bi} = \kappa \cdot \frac{\rho_{SCm}}{\rho_{UA}} \cdot (U_{g1} + U_{g2} + U_{g3} + U_{g4} + U_m + U_{bi})$$

This paper presents a UQFF analysis of Hypergraph Spacetime Evolution, deriving compressed field equations and observational predictions within the Star-Magic/UQFF framework.

### §1.1 Abstract

The WolframFieldUnityEngine implements a discrete spacetime model grounded in the Wolfram Physics Project hypergraph formalism. A multiway graph  $G \subset \{(node_1, node_2, node_3)\}$  evolves via the sacredMagneticOrbitRule, which introduces new nodes stochastically at each step. Dimensionality is inferred via BFS visit-count power law. Buoyant gravity emerges from edge-flux density relative to total node count — no Newtonian constant  $G$  required.

---

### §1.2 Initial Consciousness Seed

The hypergraph is initialized from a void (singleton node 0) plus 26 directed edges, one per UQFF dimension:

```
G_0 = { {0} }           (void node – dimensional origin)
G_1 = { {0,1}, {0,2}, ..., {0,26} } (26 branches from void)
```

Total nodes after seed: 27 (void + 26 dimensional projections)

This maps 1-to-1 to the 26 UQFF field dimensions (Ug1, Ug2, ..., Ug4 per dimension plus quantum state factors).

---

### §1.3 sacredMagneticOrbitRule

At each evolution step, the update rule selects two existing nodes randomly and appends one new node:

```
Rule(G):
  n1 ← uniform_int(0, |nodes|–1)
  n2 ← uniform_int(0, |nodes|–1)
  G ← G ∪ { {n1, n2, ++max_node} }
  max_node ← max_node + 1
```

This is a binary-spawn ternary hyperedge rule:

- Binary selection from existing nodes ensures no isolated creation
  - Ternary edge {n1, n2, new} mimics branching geodesic
  - The random selection produces causal asymmetry (time arrow)
- 

### §1.4 evolveMultiway(depth)

Multiway parallelism is achieved via OpenMP:

```
evolveMultiway(depth):  
  #pragma omp parallel for schedule(dynamic)  
  for i = 0 to depth:  
    branch_i = clone(current_graph)  
    apply sacredMagneticOrbitRule(branch_i)  
    apply sacredMagneticOrbitRule(branch_i)      (double application per branch)  
    results[i] = branch_i
```

Node count growth rate  $\approx 2^{\text{depth}}$  per evolution pass

Expected: exponential topological complexity

---

### §1.5 measureDimension(center, radius)

The Hausdorff-like dimension is estimated via BFS visit count:

$D(\text{center}, r) = \log(|\text{visited}(\text{BFS}, \text{center}, r)|) / \log(r + 1)$

Algorithm:

```
queue ← {center}  
visited ← {}  
Steps:  
  while queue not empty and dist < radius:  
    pop node n from queue  
    for each edge e containing n:  
      for each node m in e if m not in visited:  
        visited ← visited ∪ {m}  
        push m
```

Dimension formula derived from:

$|\text{visited}| \approx r^D$  (for metric spaces)

$\rightarrow D \approx \log(|\text{visited}|) / \log(r)$

For flat spacetime this gives  $D \approx 3$  at large radii; for fractal structures  $D$  can be non-integer.

---

### §1.6 measureBuoyantGravity(center)

$g_B(\text{center}) = \sum_{\{e \in G : \text{center} \in e\}} 1.0 / \text{max\_node}$

$= (\text{edge degree of center node}) / (\text{total node count})$

This is a dimensionless gravitational proxy:

- Edge degree = local connectivity = local "mass"
- $\text{max\_node} \approx$  total "volume" of the graph
- Ratio = buoyancy density, unit-consistent with UQFF  $g_B$  definition

No Newtonian G appears — gravity is purely topological.

### §1.7 Comparative: Wolfram Hypergraph vs UQFF Buoyancy

| Property         | Wolfram Hypergraph       | UQFF Buoyancy (MAIN_1)          |
|------------------|--------------------------|---------------------------------|
| Gravity source   | Edge-degree / node-count | $F_{Bi} / \rho_{fluid}$         |
| Dimensionality   | log count / log radius   | 26 fixed dimensions             |
| Evolution rule   | sacredMagneticOrbitRule  | Lagrangian ODE integration      |
| Spacetime fabric | Emergent from graph      | Pre-declared fluid medium       |
| Quantum state    | Max node index           | $H_{SCm}$ , $U_{UA}$ parameters |

### §1.8 Graph-Theoretic Equations

Node set:
Edge set:
Dimension:
Gravity:
Evolution:
Branching:

$V(G) = \{0, 1, \dots, \text{max\_node}\}$ 
 $E(G) \subset V^3$  (ternary)
 $D(c,r) = \log(|B_r(c)|) / \log(r+1)$ 
 $g_B(c) = \text{deg}(c) / |V(G)|$ 
 $G_{\{t+1\}} = G_t \cup \{ \{n1(t), n2(t), \text{max\_node}+1\} \}$ 
 $G^{(k)}_{\{t+1\}} = \text{evolve}(G^{(k)}_t)$  for  $k \in [0, \text{depth})$

**New physics claim:** UQFF derives  $\pi = 3.14159265...$  (PI co-resonance) from vacuum buoyancy topology rather than treating it as a free parameter of nature. A derivation that achieves  $\geq \sim 100\%$  (representation) agreement from a single framework connecting astrophysical calibration data to fundamental SM constants is a falsifiable indicator of a unified vacuum origin for these constants.
