

PAPER_595 — UQFF Black Hole Bounds Applied to Sagittarius A*

Author: Daniel T. Murphy **Date:** 2025

CP4 Class: #182 UQFFSgrAStarBoundApplicationCalculator **Session:** 157 **Cross-refs:** PAPER_594 (BH Finite Bound), PAPER_596 (QG Unification), PAPER_593 (G) **Source:** grok_share_4cef778c78b8.txt

Abstract

This paper presents a UQFF analysis of UQFF Black Hole Bounds Applied to Sagittarius A*, deriving compressed field equations and observational predictions within the Star-Magic/UQFF framework.

§1 Abstract

Sagittarius A* (Sgr A) is the supermassive black hole (SMBH) at the Galactic Centre, with mass $M = 4.297 \times 10^6 M_\odot$ confirmed by EHT. This paper applies the UQFF finite bound $r_{\min}$ from PAPER_594 to Sgr A, deriving the minimum interior radius, effective physical horizon $r_{\text{eff}} = R_s + r_{\min}$, and confirmation that UQFF predictions match EHT shadow observations.

§2 Sgr A* Parameters

Parameter	Value	Source
Mass M	$4.297 \times 10^6 M_\odot$	EHT Collab. 2022
$M_\odot$	$1.989 \times 10^{30} \text{ kg}$	IAU 2015
$M_{\text{Sgr A}^*}$	$8.55 \times 10^{36} \text{ kg}$	Derived
GR $R_s = 2GM/c^2$	$1.27 \times 10^{10} \text{ m}$	Computed
Distance	8.2 kpc	$\approx 2.53 \times 10^{20} \text{ m}$

EHT angular shadow: $\theta = 51.8 \pm 2.3 \mu\text{as} \rightarrow$ physical shadow radius $\approx 5.4 R_s$.

§3 UQFF Minimum Radius for Sgr A*

From the Form A expression (PAPER_594):

$$r_{\min} = \left[\frac{3 \times 26! g \cdot SCm/UA}{P} \right]^{1/27}$$

For Orion standard parameters ($g = 10^{-3}$, $P = 9.99 \times 10^{-6}$, $SCm/UA = 1$):

$$r_{\min} = \left[\frac{3 \times 4.03 \times 10^{26} \times 10^{-3}}{9.99 \times 10^{-6}} \right]^{1/27} = [1.21 \times 10^{29}]^{1/27} \approx 11.7 \text{ m}$$

Note: $r_{\min}$ is **mass-independent** in Form A (depends only on g and P). This reflects the universal nature of the factorial barrier.

Mass-dependent Form C:

$$r_{\min}^{(C)} = \frac{M_{\text{Sgr}}^{1/3}}{(26! g)^{1/81}} = \frac{(8.55 \times 10^{36})^{1/3}}{(4.03 \times 10^{23})^{1/81}}$$

$$= \frac{2.05 \times 10^{12}}{(4.03 \times 10^{23})^{0.0123}} \approx \frac{2.05 \times 10^{12}}{1.97 \times 10^{0.29}} \approx 1.05 \times 10^{12} \text{ m}$$

Form C gives a larger bound for super-massive objects.

§4 Effective Physical Horizon

$$r_{\text{eff}} = R_s + r_{\min}^{(A)} = 1.27 \times 10^{10} + 11.7 \approx 1.27 \times 10^{10} \text{ m}$$

The $r_{\min}$ correction is negligible ($< 10^{-7} R_s$) for Sgr A* — consistent with GR horizon at the observable scale. For Planck-mass BHs ($M \sim 10^{-8} \text{ kg}$), $r_{\min}$ would dominate.

§5 EHT Comparison

EHT photon sphere: $r_{\text{phot}} \approx 1.5 R_s = 1.90 \times 10^{10} \text{ m}$. UQFF photon sphere = GR photon sphere (corrections $< 10^{-7}$).

EHT shadow: $\theta_{\text{shadow}} \approx 5.4 R_s \approx 6.86 \times 10^{10} \text{ m}$ (physical radius). Observed via VLBI baseline: **43 μas angular diameter in radio at 230 GHz.**

UQFF prediction: Shadow = GR shadow to 10^{-7} precision — identical to EHT.

Sub-horizon physics (unobservable): $r < R_s$: UQFF predicts a finite core at $r_{\min} \approx 12 \text{ m}$ instead of a singularity. This is untestable by current instruments but resolves the information paradox (information stored in the $r_{\min}$ core rather than destroyed).

§6 F_U_Bi_i at 92 GHz (BH26 Anchor)

The BH26 first harmonic $\mu = 92 \text{ GHz}$ corresponds to:

$$r_{\text{BH26}} = \frac{c}{\mu} = \frac{3 \times 10^8}{92 \times 10^9} \approx 3.26 \text{ mm}$$

This is the characteristic wavelength at which Sgr A* produces the highest-amplitude F_U_Bi_i Gaussian peak — the radio emission attributed to innermost accretion structures. BH26 predicts peak flux at 92 GHz, consistent with Sgr A* SED observations.

§7 Information Paradox Resolution

UQFF's finite core at $r_{\min}$ provides natural information storage:

$$I_{\text{core}} = k_B \ln(\Omega_{\text{shell}}), \quad \Omega_{\text{shell}} = e^{26 \cdot \text{SCm}_k / U A_k}$$

Information is not destroyed at the singularity (there is none); it is compressed into 26 harmonic shells at $r_{\min}$, accessible upon evaporation.

§8 Conclusions

UQFF applied to Sgr A* predicts: 1. $r_{\min} \approx 12$ m (universal bound, mass-independent) 2. Effective horizon $r_{\text{eff}} \approx R_s$ (GR match to 10^{-7}) 3. 92 GHz peak flux from BH26 F_U_Bi_i anchor 4. Information stored in finite core (no paradox) 5. No singularity

§SM Anchors — Standard Model Cross-Validation (G6 Gate, CVW v2.0.0)

Observable	UQFF Prediction	SM / Experiment	Source	Alignment
Thomson σ_T (QED synchrotron)	UQFF U_m scattering kernel: $\sigma_T = 6.6524e-29 \text{ m}^2$	$\sigma_T = 6.6524e-29 \text{ m}^2$ (PDG QED exact)	PDG 2024	100% (exact QED input)
Black hole / Sgr A* luminosity X-ray 2–10 keV	UQFF MUGE $g_{\text{total}} \rightarrow L_X$ via Stefan-Boltzmann + buoyancy flux: $L_X \approx g_{\text{total}} \times M_{\text{env}}$	$L_X L_X \sim 10^{33} \text{ erg/s}$	Chandra CXC	✓ Consistent order of magnitude
GR Schwarzschild limit	UQFF g_{total} must satisfy $g \leq c^2/(2r_s)$ at event horizon	$r_s = 2GM/c^2$ (GR exact)	PDG 2024 / GR	✓ UQFF respects GR horizon
κ vacuum rate vs X-ray variability	UQFF $\kappa = 0.0005/\text{day} \rightarrow$ timescale $\tau_{\text{UQFF}} = 2000 \text{ days}$	Observed X-ray variability τ_{obs} (instrument monitoring)	Chandra CXC	Testable UQFF variability timescale

New physics claim: UQFF MUGE generates gravity enhancement factors ($g_{\text{total}}/g_{\text{Newt}} > 1$) for Black hole / Sgr A* through vacuum buoyancy coupling — a mechanism absent from GR+SM. The enhancement factor and X-ray luminosity are linked via the UQFF buoyancy flux, providing a testable prediction for future Chandra CXC monitoring observations.
