Abstract

NGC 3603 is the most extreme compact H II region and OB star cluster in the Milky Way, located approximately 20,000 light-years away in the Carina spiral arm. Its central cluster, containing $\sim 400,000 M_{\odot}$ of stellar material within a few parsecs, is the densest known star cluster in the Galaxy. Hubble ACS imaging reveals multiple Wolf-Rayet stars, O-type hypergiants, and early B supergiants concentrated in a core radius of ~ 0.5 pc. UQFF analysis of NGC 3603 yields $g_{\text{primary}} \approx 1.053 \times 10^{-3} \text{ m/s}^2$, with a novel **stellar wind pressure reduction term** $P(t) = P_0 \cdot \exp(-t/\tau_{\text{exp}})$ that depletes the effective mass over time as the massive stars blow away surrounding gas. This places NGC 3603 in the UQFF EM-dominated regime despite its extreme stellar density.

1. Introduction

The NGC 3603 cluster contains several of the most massive known stars, including WR 42e (estimated $\sim 120 M_{\odot}$) and multiple O3 hypergiants. The combined UV radiation and stellar winds from this central cluster produce a spectacular ionized cavity visible in Hubble observations. The stellar wind power ($\sim 10^{48}$ erg/s) creates an expanding bubble that continuously strips mass from the cluster's immediate environment. UQFF modeling of this system requires a time-dependent mass term that accounts for wind-driven feedback reducing the effective gravitational mass. The novel stellar wind pressure reduction term introduced here is directly applicable to all compact starburst systems.

2. UQFF Parameters

Parameter	Symbol	Value	Source
Cluster mass	M	$4 \times 10^5 M_{\odot} = 7.956 \times 10^{35} \text{ kg}$	HST photometry
Core radius	r	$8.998 \times 10^{15} \text{ m}$ (~ 0.3 pc)	HST
Stellar wind pressure	P_0	0.10	Normalized: 10% mass reduction
Pressure decay time	τ_{exp}	$3.156 \times 10^{13} \text{ s}$ (1 Myr)	Stellar evolution
SFR	—	$\sim 1 M_{\odot}/\text{yr}$	Initial burst
Redshift	z	0 (local)	—
M_{sf}	—	0.5	Mass still forming
v_{EM}	v	10^5 m/s	Cluster dispersion
B_{EM}	B	10^{-5} T	H II region field

Parameter	Symbol	Value	Source
Age	t	1 Myr = 3.156×10 ¹³ s	Stellar ages

3. UQFF Derivation

Master Gravity Equation

$$g_{\text{NGC3603}}(r,t) = (G \cdot M(t)) / r^2 \cdot (1 + H_0 \cdot t) \cdot (1 - P(t)) \cdot (1 + M_{\text{sf}}) \cdot (1 + f_{\text{TRZ}}) + q \cdot (v \times B) / m_p \cdot (1 + \rho_{\text{vac, [UA]}} / \rho_{\text{vac, [SCm]}}) \cdot 10^{-12}$$

where: - **P(t) = P₀·exp(-t/τ_{exp})** = stellar wind pressure reduction (**novel UQFF term**)
- M_{sf}(t) = M₀·exp(-t/τ_{SF}) — residual SFR mass growth

Numerical Evaluation

$$G \cdot M / r^2 = 6.6743\text{e-}11 \times 7.956\text{e}35 / (8.998\text{e}15)^2 \\ = 5.309\text{e}25 / 8.096\text{e}31 = 6.558\text{e-}7 \text{ m/s}^2$$

$$(1 + H_0 \cdot t) = 1 + 2.268\text{e-}18 \times 3.156\text{e}13 = 1.0000715 \approx 1.000 \text{ (local system)}$$

$$P(t=1\text{Myr}) = 0.10 \times e^{-1} = 0.0368; \text{ factor} = (1 - 0.037) = 0.963$$

$$\text{factor}_{\text{sf}} = 1.50; \text{ factor}_{\text{TRZ}} = 1.05$$

$$g_{\text{grav_total}} = 6.558\text{e-}7 \times 1.000 \times 0.963 \times 1.50 \times 1.05 = 9.944\text{e-}7 \text{ m/s}^2$$

$$a_{\text{EM}} = (1.602\text{e-}19 \times 1\text{e}5 \times 1\text{e-}5 / 1.673\text{e-}27) \times 11 \times 1\text{e-}12 \\ = (9.576\text{e-}20 / 1.673\text{e-}27) \times 11\text{e-}12 \\ = 5.724\text{e}7 \times 11\text{e-}12 = 1.053\text{e-}3 \text{ m/s}^2 \leftarrow \text{EM term dominates}$$

$$g_{\text{primary}} \approx 1.053 \times 10^{-3} \text{ m/s}^2$$

Resonant and Buoyancy UQFF

$$g_{\text{resonant}} = 1.053\text{e-}3 \times (1 + 0.0005 \times 0.57) = 1.053\text{e-}3 \text{ m/s}^2$$

$$g_{\text{buoyancy}} = 1.053\text{e-}3 \text{ m/s}^2 \text{ (gravitational correction } \ll \text{ EM)}$$

$$g_{\text{primary}} = 1.053 \times 10^{-3} \text{ m/s}^2$$

4. Novel Physics: Stellar Wind Pressure Reduction

The stellar wind pressure term P(t) introduces a novel UQFF correction for systems undergoing rapid mass loss through radiation pressure and kinetic stellar wind power:

$$P(t) = P_0 \cdot \exp(-t/\tau_{\text{exp}})$$

$$\text{At } t=0 \text{ (birth): } P = P_0 = 0.10 \rightarrow 10\% \text{ mass reduction at cluster formation}$$

$$\text{At } t=1 \text{ Myr: } P = 0.037 \rightarrow 3.7\% \text{ mass reduction}$$

$$\text{At } t=10 \text{ Myr: } P \approx 0 \rightarrow \text{cluster dispersed, term negligible}$$

This term is physically motivated by the ionization timescale of the surrounding molecular cloud. As stellar winds excavate the surrounding clump, effective mass available for Newtonian gravity decreases. UQFF predicts this feedback does NOT suppress the Aether EM term, which depends only on v and B — both maintained by the stellar cluster internal dispersion velocity.

Key result: Even in the most extreme stellar cluster known in the Milky Way, the UQFF EM ground state remains constant at $g = 1.053 \times 10^{-3} \text{ m/s}^2$.

5. Physical Interpretation

NGC 3603 represents the extreme upper limit of compact star cluster density in the Milky Way. The UQFF result $g \sim 1.053 \times 10^{-3} \text{ m/s}^2$ places it in the same electromagnetic ground state as all standard spiral galaxies. The stellar wind pressure term demonstrates that even dramatic mass-loss processes (10% mass reduction in $< 1 \text{ Myr}$) do not disturb the UQFF EM mode. This is consistent with the UQFF Geometry Invariance Theorem (PAPER_793) — here extended to **mass-loss invariance**: the Aether EM ground state is independent of ongoing mass-loss processes as long as v and B are maintained.

6. Conclusions

UQFF applied to NGC 3603 yields $g_{\text{primary}} \approx 1.053 \times 10^{-3} \text{ m/s}^2$ despite extreme stellar wind feedback. The novel stellar wind pressure reduction term $P(t) = P_0 \cdot \exp(-t/\tau_{\text{exp}})$ is introduced as a general UQFF correction applicable to all compact star clusters, H II regions, and starburst systems undergoing rapid mass loss. Combined with PAPER_793, this extends the UQFF Mass-Loss Invariance Theorem: the EM Aether ground state is invariant under both geometric distortions (warps) and ongoing mass-loss processes.
