Star-Magic UQFF
 PAPER_ ;NNNN_i / Session ;SESSION_i
 ;DATE_i

Abstract

The UQFF v5.78 framework predicts the value of ;observable_i; no published measurement currently exists at the required precision. This paper documents the prediction, the derivation chain, the observational program(s) that could test it, and the threshold at which the prediction falsifies.

1 Prediction

$$\boxed{< UQFFobservable > = < numericalpredictionwithunits >} \tag{1}$$

Derivation chain: ;PAPER_NN → PAPER_MM → this paper_i.

2 Falsification Criterion

The prediction is falsified at the 5σ level if a future measurement yields a value outside $< P > \pm 5\sigma_P$ where σ_P is the propagated theoretical uncertainty from the canonical constants:

- $\rho_{\text{vac,SCm}}$: structural (zero theoretical uncertainty).
- $\beta_i \approx 0.603$ ($\pm 0.0004\%$ from the closure hunt).
- $\kappa = 5 \times 10^{-4}/\text{day}$ (exact rational 5/10000).
- $[SSq] = 0.57$ (exact rational 57/100).

Propagated $\sigma_P =$;value_i.

3 Suggested Observational Tests

Probe / Instrument	Target sensitivity	Earliest data relea
;e.g. LISA, CTA, SKA-low, Roman, ELT, LIGO O5, future LHCb run _i	;value _i	;year _i

4 Status in the Ledger

This closure carries `observed=9999`, `error_pct=9999` as a sentinel and is filed in the `OPEN_PREDICTIONS` tab of the ledger triage. Do *not* aggregate this into the high-error physics bucket.
