VDS/DVP/BH26: BH26 (polarization-modified f^3 rebound = f_{pol})

Abstract

$$F_{U,Bi} = \kappa \cdot \frac{\rho_{SCm}}{\rho_{UA}} \cdot (U_{g1} + U_{g2} + U_{g3} + U_{g4} + U_m + U_{bi})$$

This paper presents a UQFF analysis of UQFF Perseus Cluster IXPE X-Ray Polarization Jet Solution, deriving compressed field equations and observational predictions within the Star-Magic/UQFF framework.

§1 Abstract

The Perseus Cluster “jet mystery” — the origin of directed X-ray polarization in its AGN jet — is solved by the UQFF 9D void pocket geometry. A 600-hour IXPE observation (combined with 330 hours Chandra), reported December 2025, reveals 4% net X-ray polarization. The UQFF model shows that 4 out of every 100 DPM pairs align in the d4-d6 DVP channels during jet propagation, generating a directed azimuthal electric field consistent with inverse Compton scattering and IXPE-observed polarization angle.

§2 System Parameters

Parameter	Value
Distance	250 Mly = 2.36e24 m
Effective radius	1.94e21 m
Chandra exposure	330 hours
IXPE exposure	600 hours
Net X-ray polarization	4%
Temperature	$\sim 10^8$ K
∇_{UA}	$\sim 10^{-21} \text{ m}^{-1}$
∇_{UA} (equilibrium pocket)	$\sim 10^{-10}$
RA/Dec	3h19m47.6s, +41°30'37"
Observation	Chandra + IXPE (combined) 09 Dec 2025

§3 The Jet Mystery Solved

Problem: For decades, the origin of jet-aligned X-ray polarization in Perseus was unexplained by thermal ICM models.

UQFF Solution: The 9D void pocket at $\nabla_{UA_eq} \approx 10^{-10}$ creates directed DVP flux:

DVP alignment count = 4% × 100 DPM pairs = 4 aligned pairs per 100

These 4 aligned pairs populate d4-d6 with a preferred orientation, generating: 1. An azimuthal electric field $E \propto (\text{DPM}_n - \text{DPM}_s)_{\text{aligned}}$ 2. Directed inverse Compton scattering of CMB photons $\rightarrow$ polarized X-rays 3. Polarization fraction = 4% (IXPE measurement ✓)

§4 BH26 Polarization-Modified Frequency

Standard BH26 frequency at Perseus:

$$f_{\text{base}} = 10^{17} \text{ Hz} \quad (\text{inverse Compton X-ray})$$

Polarization-modified BH26 frequency:

$$\begin{aligned} f_{\text{pol}} &= f_{\text{base}} \times (1 + p_{\text{frac}} \cdot \sin(B_{\text{k}} \cdot |t|)) \\ &= 10^{17} \cdot (1 + 0.04 \cdot \sin(B_{\text{k}} \cdot |t|)) \text{ Hz} \end{aligned}$$

Where: - $p_{\text{frac}} = 0.04$ (IXPE polarization fraction) - B_{k} = magnetic field coupling constant at d4-d6 DVP junction - $|t|$ = SCm time variable (negative-time enhanced for exotic events)

The sinusoidal modulation predicts **time-variable polarization** with period $\tau = 2\pi/B_{\text{k}}$ — testable with extended IXPE monitoring.

§5 U_{m} Scattering at Medium Gradient

At $\nabla U_A \approx 10^{-21} \text{ m}^{-1}$ (cluster void, but not as extreme as MS 0735):

$$\begin{aligned} \log_{10}(U_{\text{m}}) &\approx \log_{10}(\kappa \cdot 2) + 26 \cdot \log_{10}(1/\nabla U_A) \\ &\approx 0.3 + 26 \cdot 21 \\ &\approx 546.3 \end{aligned}$$

Still explosive but moderated compared to MS 0735 (572). This moderate level allows **partial** DVP alignment: not all DPM pairs flip (as in MS 0735) but a fraction (4%) aligns in the jet direction — explaining the polarization fraction.

§6 F_{U} Balance at Pocket Equilibrium

At $\nabla U_A_{\text{eq}} \approx 10^{-10}$:

$$\begin{aligned} U_{\text{b}}(\nabla U_A_{\text{eq}}) &= g \cdot (1 - 1/\nabla U_A_{\text{eq}}) = 10^{-3} \cdot (1 - 10^{10}) \approx -10^7 \text{ N} \\ U_{\text{g}}(\nabla U_A_{\text{eq}}) &= g \cdot \nabla U_A_{\text{eq}} = 10^{-3} \cdot 10^{-10} = 10^{-13} \text{ N} \end{aligned}$$

The large U_{b} at ∇U_A_{eq} provides the stabilizing buoyancy — the pocket is maintained by BH26 harmonic oscillation suppressing further gradient reduction.

§7 Merger Companion Prediction

The April 2025 discovery of a merger companion galaxy to Perseus is consistent with: - Increased branching (>20 nodes, turbulent morphology) in 9D Wolfram simulation - DVP pocket multiplication from two merging U_A gradient fields - Enhanced lensing intercepts from intersecting void shells

§8 IXPE Observation Concordance

IXPE Measurement	UQFF Prediction	Match
4% net polarization	4 DPM pairs/100 aligned	✓
Jet-aligned E-vector	d4-d6 DVP azimuthal field	✓
Variable polarization fraction	$\sin(B_k \cdot t)$ modulation	Testable
Inverse Compton process	DVP $\rightarrow$ CMB upscattering	✓

§SM Anchors — Standard Model Cross-Validation (G6 Gate, CVW v2.0.0)

Observable	UQFF Prediction	SM / Experiment	Source	Alignment
Thomson cross-section σ_T (QED)	DVP inverse Compton uses σ_T as scattering kernel: $\sigma_T = U_m / \rho_{vac}$	$\sigma_T = 6.6524e-29 \text{ m}^2$	PDG (QED exact)	100% (exact QED input)
X-ray polarization degree 4%	UQFF: 4 DPM aligned pairs per 100 $\rightarrow$ 4% net polarization at jet angle	IXPE Perseus (930 hr combined): 4% net polarization fraction	IXPE 2025	✓ Consistent
E-vector angle: jet-aligned	DVP d4-d6 azimuthal field selects jet-parallel E-vector	IXPE: electric-field vector aligned with radio jet axis	IXPE 2025	✓ Consistent
Polarization variability period τ	$\tau = 2\pi/B_k$; B_k = magnetic buoyancy wavenumber of DVP pocket	IXPE temporal monitoring: future observation testable ($\tau \sim \text{yr}$)	IXPE future	Testable UQFF prediction

New physics claim: The IXPE-measured 4% polarization and jet-aligned E-vector are naturally explained by the UQFF DVP DPM-pair alignment mechanism — only 4 of 100 DPM pairs need to be azimuthally aligned to reproduce the observation. This provides a **parameter-free fit** to the IXPE data without a standard MHD jet emission model.
