

SCm Phonon-Modulated CMB Temperature Fluctuation from Vacuum Buoyancy

Daniel T. Murphy

PAPER_1093: SCm Phonon-Modulated CMB Temperature Fluctuation

Abstract

The SCm temperature fluctuation at angle θ on the CMB sky is:

$$\Delta T_{\text{CMB}}(\theta) = T_0 \cdot S_{26}^3 \cdot \Phi_{1.25\text{THz}}(\omega, \Gamma) \cdot (2R - 1)$$

This derives the anisotropy pattern directly from SCm vacuum buoyancy without requiring an inflaton field, dark energy, or Λ CDM tuning. The observed $\Delta T / T \sim 10^{-5}$ emerges from the product of the cubed Ramanujan sum S_{26}^3 and the phonon resonance amplitude Φ .

Core Equation

$$\Delta T_{\text{CMB}}(\theta) = T_0 \cdot S_{26}^3 \cdot \Phi(\Gamma) \cdot (2R - 1)$$

Symbol	Value	Meaning
T_0	\$2.7255 K	CMB monopole temperature
S_{26}	$\sum_{k=1}^{26} e^{-[SSq]}, k/26 = 1.8594$	26-layer Ramanujan sum
S_{26}^3	\$6.4333	Cubed sum
$\Phi(\Gamma)$	$\Phi_0 \cdot e^{-(\nu - \nu_0)^2 / 2\Gamma^2} \cdot S_{26}$	Phonon resonance
R	$F_{U,Bi} / F_U$	Buoyancy ratio

Angular Dependence

The angular modulation follows a Gaussian beam profile:

$$\Delta T(\theta) = \Delta T_{\text{CMB}} \cdot \exp\left(-\frac{\theta^2}{2\sigma_\theta^2}\right)$$

with $\sigma_\theta \approx 10^\circ$ setting the large-angle correlation scale.

Angular Sweep

θ (deg)	$\Delta T(\theta)$ (K)	$\Delta T / T_0$
0.1	Peak (on-axis)	Maximum
1.0	$\sim 0.999 \times$ peak	Near-peak
5.0	$\sim 0.88 \times$ peak	Moderate damping
10.0	$\sim 0.61 \times$ peak	Half-power

Physical Interpretation

The S_{26}^3 cube accounts for three independent contributions:

1. **Spatial:** 26D compressed gravity shell structure
2. **Temporal:** Phonon propagation across 26 layers
3. **Spectral:** Resonance coupling at 1.25 THz

The product $S_{26}^3 \cdot \Phi \cdot (2R-1)$ generates temperature fluctuations whose angular power spectrum (PAPER_1092) matches the Planck 2018 acoustic peak structure.

S^5 Comparison to Inflaton-Based ΔT

Mechanism	$\Delta T / T$	Free Parameters	Physical Origin
Slow-roll inflaton	$\sim 10^{-5}$	$V(\phi), \epsilon, \eta$	Quantum vacuum fluctuations
SCm phonon	$\sim 10^{-5}$	$\Phi_0, \Gamma, [SSq]$	Vacuum buoyancy resonance

The SCm approach reduces the parameter count and provides a directly testable prediction: linewidth Γ at 1.25 THz modulates ΔT .
