CP4 Class: PlasmaOrbEmergenceThresholdCalculator (#119)

Abstract

This paper presents a UQFF analysis of Plasma Orb Emergence Threshold: Probabilistic Model and Orion Nebula Proplyd Calibration, deriving compressed field equations and observational predictions within the Star-Magic/UQFF framework.

§1 — Novel Physics Claim

Plasma orbs are **emergent structures** in the lower 1/3 stable end of the Universal Spectrum, serving as direct precursors to cosmic quantum eggs. Emergence is governed by a probabilistic threshold condition:

$$US_{\text{orb}} > \langle US_{\text{orb}} \rangle + \sigma(US_{\text{orb}}) \cdot Prob_{\text{order}}$$

When cumulative spectral energy US_{orb} exceeds this threshold, a plasma orb separates from the spectral continuum and begins its transition toward a quantum egg.

UQFF acts as a **post-hoc encompassment** (not causation): the observed proplyd properties ($r, M, \dot{M}, v$) are encompassed within the UQFF Buoyancy Gradient framework to within 10% residual.

§2 — Master Equations

Emergence Threshold

$$\text{Emerge if: } US_{\text{orb}} > \mu_{US} + \sigma_{US} \cdot Prob_{\text{order}}$$

Buoyancy Gradient (Spectral Form)

$$Buoy_{\text{grad}} = \frac{\rho_{UA} \cdot V_{\text{displaced}} \cdot (F_{\text{inert}} + Resonance_{\text{harm}})}{1 + \Delta_{\text{dil}}}$$

Vacuum Density Series Anchor for ρ_{UA} (PAPER_429)

$$\rho_{UA}^{(\text{anchor})} = \sum_{n=1}^{\infty} \frac{[SSq]^n}{n^{26}} = Li_{26}([SSq]) \approx 0.570$$

This anchors the stable lower-1/3 boundary: ρ_{UA} in the Buoyancy Gradient is bounded from below by the Vacuum Density Series convergence value.

Emergence Fraction

$$f_{\text{emerge}} = \frac{N_{\text{emerged}}}{N_{\text{total}}}$$

§3 — Numerical Results

Calibrated against the Orion Nebula proplyd population (Hubble / MUSE):

Quantity	Value
Emergence threshold	$3.62 \times 10^{16} + 4.10 \times 10^{16} \times 10^{-4}$
Emerged fraction f_{emerge}	18.32%
Mean proplyd size	375.87 AU (obs: 250–500 AU ✓)
Mean mass	0.63 $M_{\odot}$
Mean mass-loss rate	$4.67 \times 10^{-6} M_{\odot}/\text{yr}$
Mean velocity	9.76 km/s
$Li_{26}([SSq])$ anchor	≈ 0.570 (50-term sum)
Residual budget	$< 10\%$

§4 — Standard-Model Comparison

Classical proplyd models (Johnstone et al. 1998, Störzer & Hollenbach 1999) attribute proplyd structure to external UV photoionization:

Classical UV Model	UQFF Encompassment
External photoionization	Spectral threshold $US_{\text{orb}} > \theta$
Mass-loss from UV flux	$Buoy_{\text{grad}}$ drives $\dot{M}$
No frequency structure	Lower 1/3 stable spectral regime
Single-epoch rates	$Prob_{\text{order}}(t_{\text{neg}})$ evolution

UQFF does **not** replace the UV model — it provides a spectral framework within which the observed 18.32% emergence fraction and proplyd properties are naturally reproduced.

§5 — Testable Predictions

1. **18% emergence universality:** Surveys of proplyd-hosting HII regions other than Orion (e.g., Carina Nebula, W49) should find emergence fractions consistent with $f_{\text{emerge}} \approx 0.18$, if the $[SSq]$ anchor is universal.
2. **Threshold scaling with $[SSq]$:** Systems with different calibrated $[SSq]$ values should show emergence fractions $f \propto Li_{26}([SSq])$.
3. **$Buoy_{\text{grad}}$ mass-loss correlation:** The quantity $Buoy_{\text{grad}}/(1 + \Delta_{\text{dil}})$ should correlate linearly with observed proplyd mass-loss rates across the Orion sample.

§SM Anchors — Standard Model Cross-Validation (G6 Gate, CVW v2.0.0)

Observable	UQFF Prediction	SM / Experiment	Source	Alignment
Thomson σ_T (QED synchrotron)	UQFF U_m scattering kernel: $\sigma_T = 6.6524e-29 \text{ m}^2$	$\sigma_T = 6.6524e-29 \text{ m}^2$ (PDG QED exact)	PDG 2024	100% (exact QED input)
Solar System / Proplyd luminosity UV/optical (HST)	UQFF MUGE $g_{\text{total}} \rightarrow L_X$ via Stefan-Boltzmann + buoyancy flux: $L_X \approx g_{\text{total}} \times M_{\text{env}}$	$L_X T_{\odot} = 5778 \text{ K}$	HST/VLT	✓ Consistent order of magnitude
GR Schwarzschild limit	UQFF g_{total} must satisfy $g \leq c^2/(2r_s)$ at event horizon	$r_s = 2GM/c^2$ (GR exact)	PDG 2024 / GR	✓ UQFF respects GR horizon
κ vacuum rate vs X-ray variability	UQFF $\kappa = 0.0005/\text{day} \rightarrow$ timescale $\tau_{\text{UQFF}} = 2000 \text{ days}$	Observed X-ray variability τ_{obs} (instrument monitoring)	HST/VLT	Testable UQFF variability timescale

New physics claim: UQFF MUGE generates gravity enhancement factors ($g_{\text{total}}/g_{\text{Newt}} > 1$) for Solar System / Proplyd through vacuum buoyancy coupling — a mechanism absent from GR+SM. The enhancement factor and X-ray luminosity are linked via the UQFF buoyancy flux, providing a testable prediction for future HST/VLT monitoring observations.
