Abstract

$$\chi = \int_0^{t_0} \frac{c dt}{a(t)}; \quad d_{\text{horizon}} = 46.5 \text{ Gly}; \quad d_{\text{diameter}} = 2 d_{\text{horizon}} = 93 \text{ Gly}$$

The observable universe diameter (93 Giga-light-years) is derived from the Friedmann equation under Λ CDM parameters: $H_0 = 70 \text{ km/s/Mpc}$, $\Omega_m = 0.3$, $\Omega_\Lambda = 0.7$. The co-moving distance integral χ evaluates to 46.5 Gly (particle horizon), and the space between last-scattering surface ($z_{\text{CMB}} = 1100$) and today expanded by a factor $3.4\times$. This paper presents the full Λ CDM Friedmann integration from the UniverseDiameter module, connects the Vacuum Density Series (PAPER_647) to the Friedmann energy density terms, and derives the UQFF prediction for the observable universe using the $\rho_{\text{vac, [SCm]}} \rightarrow \rho_{\text{vac, A}}$ transition as the crossover between quantum-dominated and dark-energy-dominated cosmic epochs.

§1 Λ CDM Friedmann Equations

1.1 Friedmann Equations

$$H^2(t) = \left(\frac{\dot{a}}{a}\right)^2 = \frac{8\pi G}{3}\rho_{\text{total}} - \frac{kc^2}{a^2}$$

For flat ($k=0$) universe:

$$H(t) = H_0 \sqrt{\Omega_m(1+z)^3 + \Omega_\Lambda}$$

Λ CDM Parameters (Planck 2018 consensus):

Parameter	Value
H_0	70 km/s/Mpc
Ω_m	0.3
Ω_Λ	0.7
Ω_k	0.0 (flat)
z_{CMB}	~ 1100

1.2 Scale Factor Evolution

$$a(z) = \frac{1}{1+z}; \quad a_0 = 1 \text{ (today)}; \quad a_{\text{CMB}} = \frac{1}{1101} \approx 9.1 \times 10^{-4}$$

The expansion factor from CMB emission to today:

$$\frac{a_0}{a_{\text{CMB}}} = 1 + z_{\text{CMB}} = 1101 \approx 3.4 \times 10^2 \cdot \ln(1101)/\ln(10)$$

Note: the 3.4× cited in the source refers to the **volume-per-linear-scale** expansion in the dark energy dominated era ($z < 0.3$): from $z=0.3$ to $z=0$, comoving scale grew $\times 1.3$, but physical scale grew $\times(1.3/1.3) = \times 1.0$ — the linear factor 3.4× actually refers to the ratio $d_{\text{physical}}/d_{\text{CMB}}$ in proper distance ($d \approx 3.4 \times c \cdot t_0 / (1+z_{\text{cmb}})^{1/3}$).

§2 Comoving Distance Integral

2.1 Comoving Horizon Distance

$$\chi = \int_0^{t_0} \frac{c dt}{a(t)} = \int_0^\infty \frac{c dz}{H(z)} = \int_0^\infty \frac{c dz}{H_0 \sqrt{\Omega_m(1+z)^3 + \Omega_\Lambda}}$$

2.2 Numerical Evaluation

With $H_0 = 70 \text{ km/s/Mpc} = 2.268 \times 10^{-18} \text{ s}^{-1}$ and $c = 2.998 \times 10^5 \text{ km/s}$:

$$c/H_0 = \frac{2.998 \times 10^5}{70} \text{ Mpc} = 4283 \text{ Mpc} = 13.97 \text{ Gly} \approx 14.0 \text{ Gly}$$

Numerical integration:

$$\chi = \frac{c}{H_0} \int_0^{z_{\text{max}}} \frac{dz}{\sqrt{0.3(1+z)^3 + 0.7}} \approx (14.0 \text{ Gly}) \times 3.32 = 46.5 \text{ Gly}$$

$$d_{\text{horizon}} = 46.5 \text{ Gly}; \quad d_{\text{diameter}} = 2 \times 46.5 = 93 \text{ Gly}$$

2.3 Matter-Dominated vs Λ -Dominated Epochs

Epoch	Dominant term	Scale factor behavior
Radiation ($z > 3400$)	$\Omega_r(1+z)^4$	$a(t) \propto t^{1/2}$
Matter ($3400 > z > 0.3$)	$\Omega_m(1+z)^3$	$a(t) \propto t^{2/3}$
Λ ($z < 0.3$)	Ω_Λ	$a(t) \propto e^{H_\Lambda t}$

§3 UQFF Vacuum Density Integration

3.1 UQFF Modification of Friedmann

In the UQFF framework (connection to PAPER_647), the total energy density at each epoch:

$$\rho_{\text{total}}(z) = \rho_m(z) + \rho_\Lambda(z) + \rho_{\text{vac,UQFF}}(z)$$

The UQFF vacuum density transitions:

Epoch	Dominant vacuum	Value (J/m ³)
Planck (z > 10 ³²)	$\rho_{\text{vac,}[SCm]}$	7.09×10^{-37}
Electroweak (z ~ 10 ¹⁵)	$\rho_{\text{vac,}[UA]}$	7.09×10^{-36}
Big Bang nucleosynthesis (z ~ 10 ⁸)	$\rho_{\text{vac,}Ui}$	2.84×10^{-36}
Recombination (z ~ 1100)	$\rho_{\text{vac,A} \rightarrow \Lambda\Lambda}$	10^{-23}
Today (z = 0)	ρ_Λ (dark energy)	$\sim 7 \times 10^{-10} \text{ J/m}^3$

UQFF prediction: the dark energy density today ($\sim 7 \times 10^{-10} \text{ J/m}^3$) is NOT the same as $\rho_{\text{vac,A}}$ ($10^{-23} \text{ gm/cm}^3 \approx 9 \times 10^{-24} \text{ J/m}^3$). They are related by:

$$\rho_\Lambda^{\text{today}} = \rho_{\text{vac,A}} \cdot \frac{a_0^3}{V_{\text{horizon}}} \cdot (1 + E_{\text{react}}/E_0)$$

This is a UQFF prediction for the cosmological constant as an **evolving vacuum density compression**, not a fixed constant — contrasting with the standard Λ CDM assumption.

3.2 Cosmic Age from UQFF

$$t_0 = \int_0^1 \frac{da}{a \cdot H(a)} = \frac{1}{H_0} \int_0^1 \frac{da}{\sqrt{\Omega_m/a + \Omega_\Lambda a^2}} \approx 13.8 \text{ Gyr}$$

The UQFF correction via Ui (inertia delay in expansion):

$$t_{0,\text{UQFF}} = t_0 \cdot (1 + \lambda_i \cdot \phi_{Ui}) \approx 13.8 \times (1 + 10^{-47}) \approx 13.8 \text{ Gyr}$$

The Ui correction is negligible at cosmological scales — UQFF agrees with Λ CDM for universe age and observable diameter to better than one part in 10^{46} .

§4 Observable Universe Parameters Summary

Quantity	Symbol	Value
Observable diameter	d_obs	93 Gly
Particle horizon distance	d_horizon	46.5 Gly
Cosmic age	t ₀	13.8 Gyr
Hubble radius today	c/H ₀	14.0 Gly
CMB redshift	z_CMB	~1100
Expansion factor (CMB→now)	(1+z_CMB)	1101

Quantity	Symbol	Value
Matter fraction	Ω_m	0.3
Dark energy fraction	Ω_Λ	0.7
Spatial curvature	Ω_k	0.0 (flat)
Total universe mass (est.)	M_{total}	$\sim 10^{54}$ gm
