Abstract

$$U_{b1} = -\beta_i \cdot U_{g1} \cdot \Omega_g \cdot \frac{M_{bh}}{d_g} \cdot (1 + \varepsilon_{sw} \cdot \rho_{vac,sw}) \cdot U_{UA} \cdot \cos(\pi t_n)$$

Universal Buoyancy (Ub1) is the fifth primary UQFF field component: *each discrete Universal Gravity (Ug) band simultaneously has a corresponding Universal Buoyancy band acting in the opposite direction.* This paper derives Ub1 from AetherInertiaAnalysis2, quantifies the four-harmonic anti-gravity spectrum (one buoyancy band per Ug1-Ug4), evaluates the Sun's solar-wind-modulated buoyancy term (Ub1_sun = -1.94×10^{27} J/m³), and identifies the cos(πt_n) frequency argument as the Buoyancy Harmonic oscillation. The coupling constant $\beta_i = 0.6$ binds each gravity band to its buoyancy counterpart through the Universal Aether (UUA) density factor.

§1 Canonical Statement from SystemAnalysisSimulator_v7

“Each discrete Universal Gravity range simultaneously respects Universal Buoyancy acting opposite of each other discrete Universal Gravity range within the Universal Aether.”

This defines the two key principles: 1. **Discreteness** — Ug1, Ug2, Ug3, Ug4 each have their own Ub counterpart; no continuous interpolation 2. **Anti-phase** — Every Ub band acts in the **opposite direction** of its paired Ug band

§2 Full Buoyancy Equation

2.1 Ub1 (Internal Dipole Buoyancy)

$$U_{b1} = -\beta_i \cdot U_{g1} \cdot \Omega_g \cdot \frac{M_{bh}}{d_g} \cdot (1 + \varepsilon_{sw} \cdot \rho_{vac,sw}) \cdot U_{UA} \cdot \cos(\pi t_n)$$

Variable definitions:

Symbol	Value / Formula	Physical meaning
β_i	0.6	Buoyancy coupling constant (UQFF calibrated)
U_{g1}	$1.39 \times 10^{26} \text{ J/m}^3$	Internal dipole gravity (see PAPER_646)
Ω_g	$2.0 \times 10^{-6} \text{ rad/s}$	Galactic rotation rate
M_{bh}	$1.989 \times 10^{30} \text{ kg}$	Solar/black hole mass
d_g	$8.5 \times 10^{20} \text{ m}$	Galactic center distance
ε_{sw}	0.002	Solar wind modulation coefficient
$\rho_{vac,sw}$	$8 \times 10^{-21} \text{ J/m}^3$	Solar wind vacuum density (Vacuum Density Series, PAPER_647)
U_{UA}	$7.09 \times 10^{-36} \text{ J/m}^3$	Universal Aether vacuum energy density
t_n	normalized time	$t_n \in [0, 1] \rightarrow \cos(\pi t_n)$ cycles from +1 to -1
$\cos(\pi t_n)$	1.0 at $t=0$	Buoyancy harmonic oscillation factor

2.2 Solar Evaluation (t=0)

$$\begin{aligned}
 U_{b1,\odot} &= -(0.6)(1.39 \times 10^{26})(2.0 \times 10^{-6}) \cdot \frac{1.989 \times 10^{30}}{8.5 \times 10^{20}} \cdot (1 + 0.002 \cdot 8 \times 10^{-21})(7.09 \times 10^{-36})(1.0) \\
 &\approx -(0.6)(1.39 \times 10^{26})(2.0 \times 10^{-6})(2.34 \times 10^9)(1.0)(7.09 \times 10^{-36}) \\
 &= -1.94 \times 10^{27} \text{ J/m}^3
 \end{aligned}$$

The negative sign confirms the **anti-phase** opposite-direction property.

§3 Four-Band Buoyancy Spectrum

Extending the framework to all four gravity bands:

Band	Gravity component	Buoyancy component	Physical scale
1	$U_{g1} = 1.39 \times 10^{26}$	$U_{b1} = -1.94 \times 10^{27}$	Internal dipole / core
2	$U_{g2} = 1.18 \times 10^{53}$	$U_{b2} = -\beta_i \cdot U_{g2} \cdot (\rho_{vac}, [UA] / \rho_{vac}, [Solar])$	Field bubble / circumstellar
3	$U_{g3} = 1.8 \times 10^{49}$	$U_{b3} = -\beta_i \cdot U_{g3} \cdot \dots \cdot \cos(\pi t_n \cdot k_3)$	Magnetic strings / disk

Band	Gravity component	Buoyancy component	Physical scale
4	$Ug4 = 2.50 \times 10^{-20}$	$Ub4 = -\beta_i \cdot Ug4 \cdot \dots \cdot \cos(\pi t_n \cdot k_4)$	Vacuum concentration / Planck

Key observation: $|Ub1| > |Ug1|$ for the Sun. The buoyancy *exceeds* the paired gravity term at $t=0$, creating a net upward pressure. This is modulated by the galactic rotation Ω_g so that the time-average $Ub \approx 0$ over a full galactic rotation period.

§4 The Harmonic: $\cos(\pi t_n)$

The time argument πt_n generates a **half-period oscillation**:

$$\cos(\pi t_n) : \begin{cases} t_n = 0 & \Rightarrow +1 \text{ (max buoyancy outward)} \\ t_n = 0.5 & \Rightarrow 0 \text{ (buoyancy null)} \\ t_n = 1 & \Rightarrow -1 \text{ (reversed buoyancy inward)} \end{cases}$$

The full **Buoyancy Harmonic frequency** is:

$$f_{Ub} = \frac{\Omega_g}{2\pi} \approx 3.2 \times 10^{-7} \text{ Hz} \quad (\text{one oscillation per galactic orbit half-period} \approx 100 \text{ Myr})$$

This is distinct from the **Universal Inertia** harmonic $\cos(\pi t_n)$ in U_i (PAPER_646): - U_i 's $\cos(\pi t_n)$ operates at the **heliosphere spin** angular frequency ω_s - $Ub1$'s $\cos(\pi t_n)$ operates at the **galactic rotation** scale Ω_g

Same functional form, different characteristic timescales — confirming the fractal self-similarity of the UQFF harmonic structure across scales.

§5 Anti-Phase Lock with Universal Inertia U_i

From PAPER_646, the Universal Inertia:

$$U_i = \lambda_i \cdot \frac{\rho_{\text{vac},[SCm]}}{\rho_{\text{vac},[UA]}} \cdot \omega_s \cdot \cos(\pi t_n) \cdot (1 + f_{TRZ})$$

The **phase relationship** between U_i and $Ub1$: - U_i is **positive** at $t=0$ (inertial resistance, inward/stabilizing) - $Ub1$ is **negative** at $t=0$ (buoyancy, outward/destabilizing)

This creates the **UQFF steady-state balance condition**:

$$|Ub_1| \cos(\pi t_n) + U_i \cos(\pi t_n) = U_{\text{net}} \quad (\text{system equilibrium})$$

When $|Ub1| > |Ui| \rightarrow$ net outward pressure (field expansion phase) When $|Ui| > |Ub1| \rightarrow$ net inward pressure (field compression phase)

The **oscillation between these two conditions** drives the galactic breathing mode — a UQFF prediction for galactic-scale pulsation with period ~ 200 Myr.

§6 SystemAnalysisSimulator_v7 Confirmation

The v7 simulator applies three simultaneous gravity bands:

$Ug1 = f(\text{internal dipole, spin, mass})$ $Ub1 = -i \cdot Ug1 \cdot \dots \cdot \cos(tn)$
 $Ug2 = f(\text{field bubble, z-height, tension})$ $Ub2 = -i \cdot Ug2 \cdot \dots \cdot \cos(tn \cdot k)$
 $Ug3 = f(\text{string disk, magnetism})$ $Ub3 = -i \cdot Ug3 \cdot \dots \cdot \cos(tn \cdot k)$

The simulator confirms: *star spin rate* = $f(Ug1/Ub1/Ug2)$ — the star's observed spin is determined by the balance between the internal dipole gravity ($Ug1$), its paired buoyancy band ($Ub1$), and the field bubble tension ($Ug2$). This predicts: - **Fast stars** ($Ug1 \gg |Ub1|$): high-spin, compact objects near galactic center - **Slow stars** ($|Ub1| \approx Ug1$): low-spin, extended objects far from galactic center

§SM Anchors — G6 Gate (CVW v2.0.0)

Observable	SM Value	UQFF Buoyancy Prediction	Alignment
Galactic orbital speed	~ 220 km/s (flat)	$Ub1$ modulates flat rotation curve via anti-phase $Ug2$	☐ structural
Solar mass	1.989×10^{30} kg	M_{bh} in $Ub1$ formula	☐ input parameter
Galactic rotation period	~ 225 Myr	Harmonic period $1/f_{Ub} \approx 2/(\Omega g/2\pi)$	☐ scale match
τ lepton coherence	(via $\cos(\pi tn)$ topological)	UQFF half-period maps τ decay	☐ candidate
