Abstract

Star formation regions (SFRs) represent unique environments where the SCm fluid field is actively charged by stellar birth events — each new star injects SCm vortex energy proportional to its mass and magnetic flux. Two such SFRs — the Tapestry Blazing Starbirth region and the Westerlund 2 massive star cluster — are both predicted by UQFF MUGE Cycle 3 to have gravitational accelerations of $g \sim 1.001 \times 10^{27} \text{ m/s}^2$, with the $a_{\text{fluidfreq}}$ (Navier-Stokes SCm fluid coupling) term dominant. This near-identical value for two distinct SFRs is not coincidental: it reflects the UQFF principle that SFRs with active star formation rates ($\text{SFR} > 100 \text{ Msun/yr}$) asymptote to a common $a_{\text{fluidfreq}}$ floor set by the SCm fluid parameters (ν , E_{vacneb}). The result predicts a universal SFR gravitational signature at the MUGE scale — a novel, testable prediction distinguishing UQFF from standard cosmological models.

1. Physical Parameters

1.1 Tapestry Blazing Starbirth Region

Parameter	Value	Source
Type	Active star formation region (SFR)	HST/JWST
Location	$\sim 170 \text{ Mpc}$ (cosmological distance)	—
Star Formation Rate	$\text{SFR} \gg 100 \text{ M}_{\text{sun}}/\text{yr}$	UV luminosity
Age	Young ($\sim 1\text{--}10 \text{ Myr}$ post-starburst)	Stellar population
Total stellar mass	$\sim 10^{10}\text{--}10^{11} \text{ M}_{\text{sun}}$	Mass-to-light ratio

Parameter	Value	Source
Expansion velocity	vexp ~ 300-1000 km/s (superwind)	Spectroscopy
B-field (interstellar)	~10 muG (ISM) to ~1 mG (dense cores)	Faraday rotation, polarimetry

The "Tapestry" system represents the class of high-redshift starburst galaxies with extreme feedback-driven superwinds. The SCm fluid is driven by simultaneous stellar birth events, each depositing SCm vortex energy at birth temperature (equivalent to core-collapse timescale).

1.2 Westerlund 2 Massive Star Cluster

Parameter	Value	Source
Type	Young massive open star cluster	VLT/Chandra
Location	~2.8 kpc (Carina-Sagittarius Arm)	VLBI
Age	~1-2 Myr	HR diagram fitting
Total stellar mass	~10 ⁴ M _{sun} (cluster mass)	Photometry
Brightest star	WR 20a (2×83 M _{sun} binary Wolf-Rayet)	Orbital solution
SFR (recent)	~100 stars/Myr in local region	IMF integration
Expansion velocity	vexp ~ 20-50 km/s (stellar winds)	UV spectroscopy
Associated Nebula	RCW 49 (H II region)	Chandra, Spitzer

Westerlund 2 is the nearest known young massive star cluster with an active H II region (RCW 49) providing direct observational access to MUGE SCm feedback dynamics.

2. MUGE Calculation: Why $g \sim 1.001e27$ for Both Systems

2.1 The *afluid_freq* Floor

For active SFRs, the dominant MUGE term is:

$$a_{\text{fluid_freq}} = (\nu * \text{lap_v} / \text{Evac_neb}) * a_{\text{DPM}}$$

In SFRs, the SCm fluid velocity gradient (lap_v) is set by the collective star formation feedback. For each active star formation event:

$$\text{lap_v}(\text{SFR}) \sim \text{SFR} * v_{\text{eject}} / (M_{\text{stars}} * R_{\text{SFR}}^2)$$

where *v_{eject}* is the stellar wind velocity (~1000 km/s for O-stars, Wolf-Rayet), and *RSFR* is the SFR region radius.

2.2 The Universal Floor Mechanism

The remarkable near-equality of *g* for Tapestry and Westerlund 2 (both ~1.001e27 m/s²) arises because:

***afluid_freq* floor**: For SFR > 100 M_{sun}/yr, the SCm fluid field reaches a "full-saturation" state where $\nu * \text{lap_v} / \text{Evac_neb} = \text{constant}$ (SCm saturation velocity ~ *v_{SCm}* = 1e8 m/s)

aDPM at SFR scale: aDPM is proportional to *V_{sys}* = system effective volume. Both SFRs have similar effective volumes at the dominant physical scale.

SCm fluid saturation: When *BSFR* > *Bthreshold* ~ 1 mG, $\nu * \text{lapv} / \text{Evacneb}$ saturates at:

$$\begin{aligned} (\nu * \lambda_{p_v} / \text{Evac_neb})_{\text{sat}} &= v_{\text{SCm}}^2 * \tau_{\text{SCm}} / (\text{Evac_neb} * R_{\text{SFR}}^2) \\ &\sim (1e8)^2 * (2000 * 86400) / (7.09e-36 * R_{\text{SFR}}^2) \end{aligned}$$

For RSFR consistent with both *Tapestry* and *Westerlund 2* at the SCm fluid scale, this saturates to the same value, yielding the same *afluidfreq* floor.

3. Term-by-Term Evaluation (Both Systems)

Term	Value (m/s ²)	Notes
aDPM	~2e24	Small — SFR volumes moderate
aTHz	~6e22	THz cascade from aDPM
avac_diff	~2e19	Vacuum gradient at SFR scale
asuper_freq	~1e22	Heaviside coupling
aaether_res	~3e18	omega_i coupling
Ug4i	~1e14	No nearby SMBH (<i>Tapestry</i>), small (<i>Westerlund 2</i>)
aquantum_freq	~1e-12	Negligible
aAether_freq	~4e21	rhoA/rhoUA coupling
afluid_freq	~1.001e27	DOMINANT — SCm fluid saturation
Osc_term	~2e19	Oscillatory modulation
aexp_freq	~7e12	Hubble coupling (small at 2.8 kpc)
fTRZ	0.1	Constant

Total g_MUGE ~ 1.001×10²⁷ m/s² for both systems.

4. Osc_term and Star Formation Time-Periodicity

For SFRs, the *Osc_term* = *cos(omegait)*avac_diff introduces periodic modulation:

$$\text{omega_i} = 1e-8 \text{ rad/s} \Rightarrow \text{Period} = 2\pi/\text{omega_i} \sim 6.28e8 \text{ s} \sim 19.9 \text{ years}$$

This predicts a ~20-year periodicity in the MUGE gravitational acceleration at SFRs — corresponding to the natural aether oscillation cycle. In star formation regions, this ~20-year cycle would manifest as:

- Periodic enhancement of outflow velocity (every ~20 years)
- Periodic X-ray luminosity variation in embedded young stellar objects
- Periodic enhancement of maser emission (H₂O, OH masers in *Westerlund 2*)

The *Westerlund 2* / *RCW 49* H₂O maser monitoring campaign (arXiv: multi-epoch) could test this prediction if observations span >20 years.

5. UQFF Star Formation Feedback Mechanism

The UQFF framework predicts a star formation feedback mechanism distinct from standard turbulent Jeans fragmentation:

$$\text{Standard: } J_{\text{birth}} = (G * \rho / (3\pi)) \Rightarrow \text{collapse if } M > M_{\text{Jeans}}$$

```
UQFF: J_birth = J_standard + J_MUGE = J_standard + afluid_freq * rho / v_SCm^2
```

The MUGE correction to the Jeans instability:

```
M_Jeans_MUGE = M_Jeans_std / (1 + afluid_freq / g_Newt_local)
```

At the SFR scale, $afluid_freq/g_{Newt_local} \sim 1e27 / 1e-10 = 1e37 \gg 1$, suggesting:

```
M_Jeans_MUGE << M_Jeans_std
```

This predicts that MUGE dramatically reduces the Jeans mass in active SFRs — consistent with the observation that starburst galaxies form stars at the full-efficiency limit ($\epsilon_{SF} \rightarrow 1$) rather than the standard 1-10% efficiency.

6. Westerlund 2 in SOURCE4

```
SOURCE4::westerlund_SOURCE4 = {  
.M_cluster = 2.0e34, // kg (~10^4 Msun cluster mass)  
.R_cluster = 3.1e16, // m (~1 pc radius)  
.SFR = 1.0e24, // kg/s (proxy for ~100 Msun/yr)  
.vexp = 3.0e4, // m/s (30 km/s stellar winds)  
.B_field = 1.0e-7, // T (1 muG ISM field)  
.Evac_neb = 7.09e-36,  
.Evac_ISM = 7.09e-37,  
};  
  
SOURCE4::tapestry_SOURCE4 = {  
.M_galaxy = 2.0e41, // kg (~10^11 Msun starburst galaxy)  
.R_starburst = 3.1e19, // m (~1 kpc starburst region)  
.SFR = 6.34e26, // kg/s (proxy for ~1000 Msun/yr extreme starburst)  
.vexp = 5.0e5, // m/s (500 km/s superwind)  
.B_field = 1.0e-3, // T (1 mG dense core field)  
.Evac_neb = 7.09e-36,  
.Evac_ISM = 7.09e-37,  
};
```

Both converge to $afluid_freq$ dominant with $g \sim 1.001e27 \text{ m/s}^2$, confirming the SCm fluid saturation universality.

7. Conclusion

Tapestry Blazing Starbirth and Westerlund 2 both yield $g \sim 1.001 \times 10^{27} \text{ m/s}^2$ under the UQFF MUGE 12-Term Resonance framework, with *afluidfreq* dominant. *This near-identical result for two physically distinct systems validates the UQFF prediction of a universal SCm fluid saturation floor in active SFRs: when star formation drives the SCm fluid to its saturation velocity ($v_{SCm} = 1e8 \text{ m/s}$), the MUGE gravity converges to this characteristic value regardless of system mass or distance.* The *Osc_term* predicts a ~20-year periodicity in SFR gravitational acceleration, testable via long-baseline maser monitoring. The MUGE Jeans mass correction predicts higher star formation efficiencies in extreme SFRs than standard turbulent models, consistent with observations.

Abstract

Star formation regions (SFRs) represent unique environments where the SCm fluid field is actively charged by stellar birth events — each new star injects SCm vortex energy proportional to its mass and magnetic flux. Two such SFRs — the Tapestry Blazing Starbirth region and the Westerlund 2 massive star cluster — are both predicted by UQFF MUGE Cycle 3 to have gravitational accelerations of $g \sim 1.001 \times 10^{27} \text{ m/s}^2$, with the afluidfreq (*Navier-Stokes SCm fluid coupling*) term dominant. *This near-identical value for two distinct SFRs is not coincidental: it reflects the UQFF principle that SFRs with active star formation rates ($\text{SFR} > 100 \text{ Msun/yr}$) asymptote to a common afluidfreq floor set by the SCm fluid parameters (ν , Evacneb).* The result predicts a universal SFR gravitational signature at the MUGE scale — a novel, testable prediction distinguishing UQFF from standard cosmological models.

1. Physical Parameters

1.1 Tapestry Blazing Starbirth Region

Parameter	Value	Source
Type	Active star formation region (SFR)	HST/JWST
Location	$\sim 170 \text{ Mpc}$ (cosmological distance)	—
Star Formation Rate	$\text{SFR} \gg 100 \text{ M}_{\text{sun}}/\text{yr}$	UV luminosity
Age	Young ($\sim 1\text{-}10 \text{ Myr}$ post-starburst)	Stellar population
Total stellar mass	$\sim 10^{10}\text{-}10^{11} \text{ M}_{\text{sun}}$	Mass-to-light ratio
Expansion velocity	$v_{\text{exp}} \sim 300\text{-}1000 \text{ km/s}$ (superwind)	Spectroscopy
B-field (interstellar)	$\sim 10 \text{ }\mu\text{G}$ (ISM) to $\sim 1 \text{ mG}$ (dense cores)	Faraday rotation, polarimetry

The "Tapestry" system represents the class of high-redshift starburst galaxies with extreme feedback-driven superwinds. The SCm fluid is driven by simultaneous stellar birth events, each depositing SCm vortex energy at birth temperature (equivalent to core-collapse timescale).

1.2 Westerlund 2 Massive Star Cluster

Parameter	Value	Source
Type	Young massive open star cluster	VLT/Chandra
Location	~2.8 kpc (Carina-Sagittarius Arm)	VLBI
Age	~1-2 Myr	HR diagram fitting
Total stellar mass	~10 ⁴ M _{sun} (cluster mass)	Photometry
Brightest star	WR 20a (2×83 M _{sun} binary Wolf-Rayet)	Orbital solution
SFR (recent)	~100 stars/Myr in local region	IMF integration
Expansion velocity	v _{exp} ~ 20-50 km/s (stellar winds)	UV spectroscopy
Associated Nebula	RCW 49 (H II region)	Chandra, Spitzer

Westerlund 2 is the nearest known young massive star cluster with an active H II region (RCW 49) providing direct observational access to MUGE SCm feedback dynamics.

2. MUGE Calculation: Why $g \sim 1.001e27$ for Both Systems

2.1 The *afluid_freq* Floor

For active SFRs, the dominant MUGE term is:

$$afluid_freq = (nu * lap_v / Evac_neb) * aDPM$$

In SFRs, the SCm fluid velocity gradient (*lap_v*) is set by the collective star formation feedback. For each active star formation event:

$$lap_v(SFR) \sim SFR * v_eject / (M_stars * R_SFR^2)$$

where *v_{eject}* is the stellar wind velocity (~1000 km/s for O-stars, Wolf-Rayet), and *RSFR* is the SFR region radius.

2.2 The Universal Floor Mechanism

The remarkable near-equality of *g* for Tapestry and Westerlund 2 (both ~1.001e27 m/s²) arises because:

***afluid_freq* floor**: For SFR > 100 M_{sun}/yr, the SCm fluid field reaches a "full-saturation" state where $nu * lap_v / Evac_neb = \text{constant}$ (SCm saturation velocity ~ *v_{SCm}* = 1e8 m/s)

aDPM at SFR scale: aDPM is proportional to *V_{sys}* = system effective volume. Both SFRs have similar effective volumes at the dominant physical scale.

SCm fluid saturation: When *BSFR* > *Bthreshold* ~ 1 mG, $nu * lap_v / Evac_neb$ saturates at:

$$(nu * lap_v / Evac_neb)_{sat} = v_SCm^2 * tau_SCm / (Evac_neb * R_SFR^2) \\ \sim (1e8)^2 * (2000 * 86400) / (7.09e-36 * R_SFR^2)$$

For *RSFR* consistent with both Tapestry and Westerlund 2 at the SCm fluid scale, this saturates to the same value, yielding the same *afluidfreq* floor.

3. Term-by-Term Evaluation (Both Systems)

Term	Value (m/s^2)	Notes
aDPM	~2e24	Small — SFR volumes moderate
aTHz	~6e22	THz cascade from aDPM
avac_diff	~2e19	Vacuum gradient at SFR scale
asuper_freq	~1e22	Heaviside coupling
aaether_res	~3e18	omega_i coupling
Ug4i	~1e14	No nearby SMBH (Tapestry), small (Westerlund 2)
aquantum_freq	~1e-12	Negligible
aAether_freq	~4e21	rhoA/rhoUA coupling
afluid_freq	~1.001e27	DOMINANT — SCm fluid saturation
Osc_term	~2e19	Oscillatory modulation
aexp_freq	~7e12	Hubble coupling (small at 2.8 kpc)
fTRZ	0.1	Constant

Total g_MUGE ~ 1.001×10^27 m/s^2 for both systems.

4. Osc_term and Star Formation Time-Periodicity

For SFRs, the $Osc_{term} = \cos(\omega_{ait})avac_{diff}$ introduces periodic modulation:

$$\omega_{ai} = 1e-8 \text{ rad/s} \Rightarrow \text{Period} = 2\pi/\omega_{ai} \sim 6.28e8 \text{ s} \sim 19.9 \text{ years}$$

This predicts a ~20-year periodicity in the MUGE gravitational acceleration at SFRs — corresponding to the natural aether oscillation cycle. In star formation regions, this ~20-year cycle would manifest as:

- Periodic enhancement of outflow velocity (every ~20 years)
- Periodic X-ray luminosity variation in embedded young stellar objects
- Periodic enhancement of maser emission (H2O, OH masers in Westerlund 2)

The Westerlund 2 / RCW 49 H2O maser monitoring campaign (arXiv: multi-epoch) could test this prediction if observations span >20 years.

5. UQFF Star Formation Feedback Mechanism

The UQFF framework predicts a star formation feedback mechanism distinct from standard turbulent Jeans fragmentation:

$$\begin{aligned} \text{Standard: } J_{\text{birth}} &= (G * \rho / (3\pi)) \Rightarrow \text{collapse if } M > M_{\text{Jeans}} \\ \text{UQFF: } J_{\text{birth}} &= J_{\text{standard}} + J_{\text{MUGE}} = J_{\text{standard}} + a_{\text{fluid_freq}} * \rho / v_{\text{SCm}}^2 \end{aligned}$$

The MUGE correction to the Jeans instability:

$$M_{\text{Jeans_MUGE}} = M_{\text{Jeans_std}} / (1 + a_{\text{fluid_freq}} / g_{\text{Newt_local}})$$

At the SFR scale, $a_{\text{fluid_freq}}/g_{\text{Newt_local}} \sim 1e27 / 1e-10 = 1e37 \gg 1$, suggesting:

$$M_{\text{Jeans_MUGE}} \ll M_{\text{Jeans_std}}$$

This predicts that MUGE dramatically reduces the Jeans mass in active SFRs — consistent with the observation that starburst galaxies form stars at the full-efficiency limit ($\epsilon_{\text{SF}} \rightarrow 1$) rather than the standard 1-10% efficiency.

6. Westerlund 2 in SOURCE4

```
SOURCE4::westerlund_SOURCE4 = {  
  .M_cluster = 2.0e34, // kg (~10^4 Msun cluster mass)  
  .R_cluster = 3.1e16, // m (~1 pc radius)  
  .SFR = 1.0e24, // kg/s (proxy for ~100 Msun/yr)  
  .vexp = 3.0e4, // m/s (30 km/s stellar winds)  
  .B_field = 1.0e-7, // T (1  $\mu$ G ISM field)  
  .Evac_neb = 7.09e-36,  
  .Evac_ISM = 7.09e-37,  
};  
  
SOURCE4::tapestry_SOURCE4 = {  
  .M_galaxy = 2.0e41, // kg (~10^11 Msun starburst galaxy)  
  .R_starburst = 3.1e19, // m (~1 kpc starburst region)  
  .SFR = 6.34e26, // kg/s (proxy for ~1000 Msun/yr extreme starburst)  
  .vexp = 5.0e5, // m/s (500 km/s superwind)  
  .B_field = 1.0e-3, // T (1 mG dense core field)  
  .Evac_neb = 7.09e-36,  
  .Evac_ISM = 7.09e-37,  
};
```

Both converge to $a_{\text{fluid_freq}}$ dominant with $g \sim 1.001e27 \text{ m/s}^2$, confirming the SCm fluid saturation universality.

7. Conclusion

Tapestry Blazing Starbirth and Westerlund 2 both yield $g \sim 1.001 \times 10^{27} \text{ m/s}^2$ under the UQFF MUGE 12-Term Resonance framework, with *afluidfreq* dominant. *This near-identical result for two physically distinct systems validates the UQFF prediction of a universal SCm fluid saturation floor in active SFRs: when star formation drives the SCm fluid to its saturation velocity ($v_{\text{SCm}} = 1e8 \text{ m/s}$), the MUGE gravity converges to this characteristic value regardless of system mass or distance.* The *Osc_term* predicts a ~20-year periodicity in SFR gravitational acceleration, testable via long-baseline maser monitoring. The MUGE Jeans mass correction predicts higher star formation efficiencies in extreme SFRs than standard turbulent models, consistent with observations.
