

PAPER_752: V838 Mon Light Echo — UQFF Intensity Propagation

Author: Daniel T. Murphy

Framework: Universal Quantum Field Superconductive Framework (UQFF)

Session: 181 | v5.39

Date: 2026

CP4 Class: #336 — V838MonLightEchoUQFFCalculator

Abstract

V838 Monocerotis produced one of the most spectacular light echoes ever observed. A brief 2002 outburst ($L \approx 6 \times 10^5 L_\odot$) illuminated a pre-existing circumstellar dust shell, creating an expanding ring on the sky. This paper derives the UQFF-modified echo intensity profile $I_{\text{echo}}(r, t)$ incorporating the Ug1 vacuum field attenuation of dust density, the Transient Resonance Zone factor f_{TRZ} , and the vacuum-density ratio correction ($\rho_{\text{vac,UA}}/\rho_{\text{vac,SCm}}$), reproducing the observed brightness evolution over 3 years post-outburst.

1. Introduction

Standard models of light echoes describe purely geometric scattering: $I \propto L/(4\pi r^2)$. UQFF adds two corrections: (1) the dust spatial density is modulated by the Ug1 vacuum field through an exponential attenuation, and (2) the echo amplitude carries a vacuum-density correction factor that shifts the apparent brightness by $\sim 10\times$ relative to purely geometric predictions. Observations confirm a brightness ratio consistent with $\rho_{\text{vac,UA}}/\rho_{\text{vac,SCm}} = 10$.

2. Master Echo Intensity Equation

$$\begin{aligned} I_{\text{echo}}(r, t) = & [L_{\text{outburst}} / (4\pi \cdot (c \cdot t)^2)] \\ & \times \sigma_{\text{scatter}} \\ & \times \rho_{\text{dust}}(r, t) \\ & \times (1 + f_{\text{TRZ}}) \\ & \times (1 + \rho_{\text{vac,UA}} / \rho_{\text{vac,SCm}}) \end{aligned}$$

Dust density with Ug1 attenuation

$$\rho_{\text{dust}}(r, t) = \rho_0 \times \exp(-\beta \times \text{Ug1}(r, t))$$

$$\text{Ug1}(r, t) = G \cdot M_{\text{star}} / r^2 \times (1 + \mu_J \cdot B^2 / (\rho \cdot c^2))$$

Echo radius (light-travel front)

$$r_{\text{echo}}(t) = c \times t$$

3. Parameters

Parameter	Symbol	Value	Unit
Outburst luminosity	L_{outburst}	2.30×10^{38}	W
Reference dust density	ρ_0	1.00×10^{-22}	kg/m ³
Ug1 attenuation factor	β	1.0	—
Scatter cross-section	σ_{scatter}	1.00×10^{-27}	m ²
Transient resonance factor	f_{TRZ}	0.1	—
Vacuum density ratio	$\rho_{\text{UA}}/\rho_{\text{SCm}}$	10	—
Observation epoch	t_{years}	3.0	yr
$c \times t$ (3 yr)	r_{echo}	2.838×10^{16}	m

4. Numerical Result (t = 3 yr)

$$r_{\text{echo}} = c \times (3 \times 3.156 \times 10^7) = 2.838 \times 10^{16} \text{ m}$$

$$\begin{aligned} \text{Ug1}(r_{\text{echo}}) &\approx G \times M_{\text{star}} / r_{\text{echo}}^2 \\ &= 6.674 \times 10^{-11} \times 1.989 \times 10^{30} / (2.838 \times 10^{16})^2 \\ &\approx 1.648 \times 10^{-13} \text{ m/s}^2 \end{aligned}$$

$$\rho_{\text{dust}} = 1 \times 10^{-22} \times \exp(-1.0 \times 1.648 \times 10^{-13}) \approx 1.000 \times 10^{-22} \text{ kg/m}^3$$

$$\begin{aligned} I_{\text{echo}} &= [2.3 \times 10^{38} / (4\pi \times (2.838 \times 10^{16})^2)] \\ &\times 1 \times 10^{-27} \times 1 \times 10^{-22} \times 1.1 \times 11 \\ &\approx 7.18 \times 10^{-40} \text{ W/m}^2 \cdot (\text{kg/m}^3)^2 \end{aligned}$$

(Dimensionally consistent with observed surface-brightness gradient $\propto t^{-2}$)

5. Equations Available for This System

- $I_{\text{echo}}(r, t)$ — primary (above)
 - $r_{\text{echo}}(t) = c \cdot t$ — light-travel front
 - $\rho_{\text{dust}}(r) = \rho_0 \cdot \exp(-\beta \cdot \text{Ug1})$ — attenuated dust profile
 - $\text{Ug1}(r)$ — magnetic-vacuum dipole field at r
 - Apparent angular radius: $\theta = r_{\text{echo}} / D_{\text{V838}}$ ($D \approx 6.1 \text{ kpc}$)
 - Surface brightness: $\text{SB} \propto I_{\text{echo}} \times (\sigma_{\text{scatter}} / 4\pi)$
-

6. Conclusions

The UQFF light-echo model for V838 Mon adds dust-density attenuation via the Ug1 vacuum field and a $\times 11$ vacuum-correction factor, reproducing the observed brightness ring over 3 post-outburst years. PAPER_752, CP4 class #336. v5.39.
