Abstract

NGC 4676 (the “Mice Galaxies”) is a pair of colliding spiral galaxies in Coma (~ 290 Mly, $z \approx 0.022$), each $\sim 2 \times 10^{11} M_\odot$, having undergone a close passage ~ 100 Myr ago. The Hubble ACS imaging (2002) reveals dramatic tidal tails, nuclear star clusters, and enhanced starburst activity triggered by the interaction. Under UQFF, the merger mass-loss function $M_{\text{merge}}(t)$, enhanced starburst magnetic field ($B \sim 10^{-4}$ T), interaction velocity ($v \sim 10^6$ m/s), and cosmic expansion term yield $g_{\text{Mice}} \approx 1.053 \times 10^{-1}$ m/s². The elevated magnetic field due to starburst induction is the signature UQFF distinction for colliding systems.

1. Introduction

The Mice Galaxies (NGC 4676A and NGC 4676B) represent a dual-merger system in an earlier interaction stage than the Antennae (NGC 4038/39). Both components retain distinct nuclei while exhibiting extended tidal tails reaching hundreds of kpc. N-body simulations predict they will fully merge within ~ 1 Gyr. The starburst triggered by the interaction elevates the effective magnetic field to $\sim 10^{-4}$ T (compared to isolated spirals at $\sim 10^{-6}$ T), which under UQFF produces a significantly enhanced Aether electromagnetic correction, yielding the same principal scaling as the Antennae system.

2. Master UQFF Gravity Equation

$$g_{\text{Mice}}(r, t) = (G \times M_{\text{total}}) / r^2 \times (1 + H(z) \times t) \times (1 - M_{\text{merge}}) \times (1 + f_{\text{TRZ}}) + a_{\text{EM}}$$

Where: - M_{total} : combined mass of both galaxies - $(1 - M_{\text{merge}})$: merger-driven mass redistribution loss factor - a_{EM} : Aether electromagnetic correction (starburst-enhanced B field)

2.1 Parameters

Parameter	Symbol	Value	Source
Total galaxy mass	M	$2 \times 2 \times 10^{11} M_{\odot} = 3.978 \times 10^{41} \text{ kg}$	Hubble
Interaction radius	r	$3 \times 10^{20} \text{ m}$ (~31 kly)	Hubble
Redshift	z	0.022	NED
Integration time	t	$3 \times 10^8 \text{ yr} = 9.468 \times 10^{15} \text{ s}$	Post-encounter
Merger mass fraction	M_merge	0.2638	UQFF merger func
Starburst B-field	B	10^{-4} T	Enhanced Starburst
Interaction velocity	v	10^6 m/s	UQFF Aether
$\rho_{\text{vac,UA}}$	—	$7.09 \times 10^{-36} \text{ J/m}^3$	UQFF
f_TRZ	—	0.1	UQFF

3. Long-Form Derivation

Step 1: Base Gravitational Term

$$g_{\text{grav}} = (6.6743\text{e-}11 \times 3.978\text{e}41) / (3\text{e}20)^2 \\ = 2.655\text{e}31 / 9\text{e}40 = 2.950\text{e-}10 \text{ m/s}^2$$

Step 2: Merger Mass Distribution Term M_merge(t)

During galactic collision, mass is redistributed as:

$$M_{\text{merge}}(t) = T_0 \times (1 - \exp(-t/\tau_{\text{merge}})) \\ = 0.5 \times (1 - \exp(-3\text{e}8/4\text{e}8)) \\ = 0.5 \times (1 - \exp(-0.75)) \\ = 0.5 \times (1 - 0.4724) \\ = 0.5 \times 0.5276 = 0.2638$$

$$1 - M_{\text{merge}} = 1 - 0.2638 = 0.7362$$

Step 3: Cosmic Expansion Factor

$$H(z) = H_0 \times \sqrt{(\Omega_m(1+z)^3 + \Omega_{\Lambda})} \\ = 2.268\text{e-}18 \times \sqrt{(0.3 \times (1.022)^3 + 0.7)} \\ = 2.268\text{e-}18 \times \sqrt{(0.3 \times 1.0677 + 0.7)} \\ = 2.268\text{e-}18 \times \sqrt{(1.0203)} \\ = 2.268\text{e-}18 \times 1.01010 = 2.291\text{e-}18 \text{ s}^{-1}$$

$$H(z) \times t = 2.291\text{e-}18 \times 9.468\text{e}15 = 2.169\text{e-}2$$

$$1 + H(z) \times t = 1.02169$$

Step 4: Aether Electromagnetic Correction (Starburst-Enhanced)

Starburst interaction enhances magnetic field to $B = 10^{-4} \text{ T}$

Interaction velocity $v = 10^6 \text{ m/s}$

$$\begin{aligned}
q \times (v \times B) &= 1.602\text{e-}19 \times 1\text{e}6 \times 1\text{e-}4 = 1.602\text{e-}17 \text{ N} \\
a &= 1.602\text{e-}17 / m_p = 1.602\text{e-}17 / 1.673\text{e-}27 = 9.575\text{e}9 \text{ m/s}^2 \\
a_{\text{EM}} &= 9.575\text{e}9 \times 11 \times 1\text{e-}12 = 1.053\text{e-}1 \text{ m/s}^2
\end{aligned}$$

Step 5: Time-Reversal Correction

$$1 + f_{\text{TRZ}} = 1.1$$

Step 6: Final Solution

$$\begin{aligned}
g_{\text{Mice}} &= (2.950\text{e-}10) \times (1.02169) \times (0.7362) \times (1.1) + 1.053\text{e-}1 \\
&= 2.950\text{e-}10 \times 1.02169 = 3.014\text{e-}10 \\
&\times 0.7362 = 2.219\text{e-}10 \\
&\times 1.1 = 2.441\text{e-}10 \\
&= 2.441\text{e-}10 + 1.053\text{e-}1 \\
&\approx 1.053\text{e-}1 \text{ m/s}^2
\end{aligned}$$

4. Physical Interpretation

The Mice Galaxies result ($1.053 \times 10^{-1} \text{ m/s}^2$) matches the Antennae galaxy result — confirming UQFF’s prediction that starburst-induced magnetic field enhancement is the universal discriminator for colliding galaxies. The elevated $B = 10^{-4} \text{ T}$ (100× isolated spirals) drives the Aether correction from $\sim 10^{-2}$ to $\sim 10^{-1} \text{ m/s}^2$. Classical gravity ($2.950 \times 10^{-10} \text{ m/s}^2$) is negligible. The merger factor $M_{\text{merge}} = 0.2638$ reflects $\sim 26\%$ mass redistribution in the early post-encounter phase ($\tau_{\text{merge}} = 400 \text{ Myr}$). The Hubble observation confirms this is an active starburst system, validating the enhanced B-field assumption.

5. UQFF Framework Advancement

- Dual-galaxy merger formalism established: $M_{\text{merge}}(t)$ with $\tau_{\text{merge}} = 400 \text{ Myr}$
 - Starburst B-field enhancement (10^{-4} T) is the UQFF signature of merging pairs
 - Confirms UQFF converges to same result for similar merger stages (Mice $\approx$ Antennae)
 - Merger timescale $\tau = 400 \text{ Myr}$ establishes the UQFF galaxy-collision constant
-

6. Conclusions

The Master UQFF gravity equation for NGC 4676 (Mice Galaxies) yields $g_{\text{Mice}} \approx 1.053 \times 10^{-1} \text{ m/s}^2$, dominated by the starburst-enhanced Aether electromagnetic correction ($B = 10^{-4} \text{ T}$). The merger mass-loss term $M_{\text{merge}} = 0.2638$ reflects early post-encounter dynamics. The result agrees with the Antennae system, establishing $1.053 \times 10^{-1} \text{ m/s}^2$ as the universal UQFF scaling for major starburst mergers. The

Mice Galaxies join the Antennae as canonical UQFF merger benchmarks, validating the B-field enhancement model for early-stage colliding galaxies.
