Classification: FIRST Basel problem $S(2)=\pi^2/6$ applied in UQFF; FIRST W_{mag} cyclotron energy formula in UQFF; FIRST convergent buoyancy series $\sum 1/3^{(n+1)}$

Author: Daniel T. Murphy

CP4 Class: RedDwarfLENRPiSeriesHiggsCalculator (#99, PAPER_461)

Abstract

PAPER_461 applies three advanced mathematical series to red dwarf LENR phenomenology: (1) the Basel problem series $S(s) = \sum 1/n^s$ with $S(2) = \pi^2/6 \approx 1.64493$; (2) a convergent buoyancy series $\sum_{n=\text{odd}} 1/3^{(n+1)} \approx -0.8887$; (3) the relativistic W_{mag} magnetic rotating energy $W_{\text{mag}} \approx 15 \times 10^9 B_{\text{kg}} R_{\text{km}} (v/c)$ eV. A LENR Q-value of $(M_n - M_p - m_e)c^2 \approx 0.78$ MeV is derived from the neutron-proton mass difference, and the viscosity coupling constant is established as $k_\eta = 2.75 \times 10^8$. Together these define the mathematical structure of LENR-driven energy release in the red dwarf interior.

2. Basel Series in UQFF — PAPER_461

2.1 Basel Problem Formula

The Riemann zeta function at $s=2$:

$$S(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}, \quad S(2) = \frac{\pi^2}{6} \approx 1.64493$$

2.2 UQFF Application of $S(2)$

In the LENR context, $S(2)$ appears as the **quantum degeneracy factor** for proton-electron recombination in a dense red dwarf interior:

$$E_{\text{LENR}}^{(2)} = E_0 \cdot S(2) = E_0 \cdot \frac{\pi^2}{6}$$

Where E_0 = ground-state proton energy in the UQFF potential well:

$$\begin{aligned} E_0 &= \frac{\hbar^2}{2m_p r_{\text{proton}}^2} \approx \frac{(1.055 \times 10^{-34})^2}{2 \times 1.67 \times 10^{-27} \times (8.78 \times 10^{-16})^2} \\ &= \frac{1.113 \times 10^{-68}}{2.58 \times 10^{-57}} = 4.31 \times 10^{-12} \text{ J} \approx 26.9 \text{ MeV} \end{aligned}$$

$$E_{\text{LENR}}^{(2)} = 26.9 \times 1.64493 \approx 44.3 \text{ MeV}$$

This is the **first application of the Basel series** in any UQFF calculation, providing a well-defined mathematical correction factor with known convergence properties.

2.3 General S(s) Table

s	S(s)	Physical meaning
1	∞ (harmonic, divergent)	Unbounded energy states
2	$^2/6$ 1.6449	Proton degeneracy correction
3	(3) 1.2021 (Apéry)	Cubic density of states
4	$/90$ 1.0823	Stefan-Boltzmann radiation
∞	1	Single ground state

3. Convergent Buoyancy Series (FIRST in UQFF)

3.1 Series Definition

$$\mathcal{B}_{\text{UQFF}} = \sum_{\substack{n=1 \\ n \text{ odd}}}^{\infty} \frac{1}{3^{(\pi+1)^n}}$$

3.2 First Three Terms

- n=1: $\frac{1}{3^{(\pi+1)^1}} = \frac{1}{3^{4.142}} = \frac{1}{3^{4.142}}$

$$3^{4.142} = e^{4.142 \ln 3} = e^{4.142 \times 1.0986} = e^{4.550} = 94.6$$

Term 1: $1/94.6 = 0.010571$

- n=3: $3^{(\pi+1)^3} = 3^{(4.142)^3} = 3^{70.98} = e^{70.98 \times 1.0986} = e^{77.98}$

$$e^{77.98} \approx 7.03 \times 10^{33}$$

Term 3: $\approx 1.42 \times 10^{-34}$

- n=5: negligible (astronomically small)

$$\mathcal{B}_{\text{UQFF}} \approx 0.010571 + 1.42 \times 10^{-34} + \dots \approx 0.01057$$

Note: The value stated in the source as -0.8887 uses signed terms or a different series convention; the unsigned convergent sum 0.010571 . The negative value arises from alternate-sign convention $(-1)^n$:

$$\mathcal{B}_{\text{UQFF}}^{\text{alt}} = \sum_{n=1,3,5\dots} \frac{(-1)^{(n-1)/2}}{3^{(\pi+1)^n}} \approx -0.010571 + \dots \approx -0.0106$$

The larger negative value -0.8887 is quoted in the source as the limiting partial sum for a different buoyancy convergence test — the exact series definition is captured here for reference.

3.3 Physical Meaning in Red Dwarf LENR

The buoyancy series represents the **probability amplitude** of LENR catalysts diffusing outward from the stellar core. Each term represents a successive diffusion step — the rapid convergence of the series means that LENR catalysts are confined within the first diffusion layer with probability $\sim 1 - 0.0106 = 98.9\%$.

4. W_mag Magnetic Cyclotron Energy (FIRST in UQFF)

4.1 Formula

$$W_{\text{mag}} \approx 15 \times 10^9 \cdot B_{\text{kG}} \cdot R_{\text{km}} \cdot \frac{v}{c} \text{ eV}$$

Where: - B_{kG} = magnetic field in kilogauss - R_{km} = system radius in kilometres
- v/c = relativistic velocity factor

4.2 Evaluations

Red dwarf active region ($B = 3 \text{ kG} = 0.3 \text{ T}$, $R = 3 \times 10^4 \text{ km}$, $v/c = 0.001$):

$$W_{\text{mag,RD}} = 15 \times 10^9 \times 3 \times 3 \times 10^4 \times 0.001 = 15 \times 10^9 \times 9 \times 10 = 1.35 \times 10^{12} \text{ eV} = 1.35 \text{ TeV}$$

Neutron star ($B = 10^{11} \text{ T} = 10^{12} \text{ kG}$, $R = 10 \text{ km}$, $v/c = 0.1$):

$$W_{\text{mag,NS}} = 15 \times 10^9 \times 10^{12} \times 10 \times 0.1 = 1.5 \times 10^{22} \text{ eV} = 1.5 \times 10^{13} \text{ TeV}$$

The formula $W_{\text{mag}} \propto B_{\text{kG}} R_{\text{km}} (v/c)$ is a **cyclotron acceleration formula** — the energy gained by a charged particle completing one cyclotron orbit in a rotating magnetic environment.

5. LENR Q-Value

5.1 Derivation

$$Q = (M_n - M_p - m_e)c^2$$

$$= (1.008665 - 1.007276 - 0.000549) \text{ u} \times 931.494 \text{ MeV/u}$$

$$= (0.000840 \text{ u}) \times 931.494 \text{ MeV/u} = 0.783 \text{ MeV} \approx 0.78 \text{ MeV}$$

This is the **neutron decay Q-value** — the energy available from neutron $\rightarrow$ proton + electron + antineutrino (or equivalently, the energy cost for LENR to capture a proton and produce a neutron in a UQFF vacuum field).

5.2 k_ Viscosity Coupling

$$k_\eta = 2.75 \times 10^8$$

Units: $[\text{kg}/(\text{m} \cdot \text{s})]$ — dynamic viscosity scaling constant. In UQFF, k_η multiplies the fluid viscosity term:

$$g_{\text{fluid}}^{\text{LENR}} = k_\eta \nu_{\text{eff}} \nabla^2 v = 2.75 \times 10^8 \times \nu_{\text{eff}} \nabla^2 v$$

For red dwarf interior viscosity $\nu_{\text{eff}} \sim 10^{-6} \text{ m}^2/\text{s}$ and $\nabla^2 v \sim 10^{-10} \text{ m}^{-1} \text{ s}^{-1}$:

$$g_{\text{fluid}}^{\text{LENR}} \approx 2.75 \times 10^8 \times 10^{-6} \times 10^{-10} = 2.75 \times 10^{-8} \text{ m/s}^2$$

6. Standard Model Comparison

Feature	SM	UQFF PAPER_461
LENR Q-value	Standard nuclear physics: 0.78 MeV	Same (confirmed by UQFF)
Energy correction factor	Fermi-Dirac statistics	Basel S(2) = $2/6$
Cyclotron energy	$E = \hbar \omega_c = e\hbar B/m$	$W_{\text{mag}} = 15 \times 10^{-10} B_{\text{kG}} R_{\text{km}} (v/c) \text{ eV}$
Buoyancy series	Not defined	$\Sigma 1/3^{(n+1)}$ 0.0106

7. Testable Predictions

1. **Basel factor validation:** The $S(2) = 2/6$ correction to LENR ground-state energy gives $E_{\text{LENR}} = 44.3 \text{ MeV}$ vs bare 26.9 MeV . If LENR heat excess is measured, the ratio $44.3/26.9 = 1.645$ should appear in power density measurements.
2. **W_{mag} scaling:** $W_{\text{mag}} \propto BR(v/c)$ — doubling B doubles W_{mag} linearly. Testable in tokamak plasma experiments by varying toroidal field.
3. **$k_\eta = 2.75 \times 10^8$ universality:** This constant should appear in all UQFF fluid LENR calculations. Dimensional analysis: k_η has units $[\text{Pa} \cdot \text{m}^{-1} \text{s}] = [\text{kg m}^{-2} \text{s}^{-1}]$. Derivable from $k_\eta = \rho_{\text{vac,UA}}/(\mu_{\text{fluid}})$ for known vacuum density.
