PAPER_017: Redshift Corrections (z=1) in UQFF GW Propagation

Authors: Daniel Murphy & UQFF Research Collective **Date:** 2026-03-07 **Domain:** 1.2 — Gravitational Waves — LISA Future Detector **Primary Validation File:** validate_lisa_extended.py **Calibration constants:** $\kappa = 0.0005/\text{day}$, $[\text{SSq}] = 0.57$

Abstract

We derive UQFF corrections to gravitational wave strain amplitude for sources at cosmological redshift $z = 0.5, 1.0$, and 2.0 . For a $10^6 M_\odot$ supermassive black hole (SMBH) binary at $z = 1$ ($D_L = 6.42$ Gpc), UQFF predicts a 39.5% strain reduction and SNR drop from 205,910 to 128,338 relative to GR. Over a 12-month LISA observation at 1–10 mHz, the UQFF waveform lags GR by 0.63 rad (0.1 cycles) at merger. Redshift scaling shows amplitude reduction is nearly flat at 31–32% for $z = 0.5$ – 2.0 , indicating that UQFF damping is primarily distance-independent (aether-dominated) in this regime.

UQFF Discovery: Novel application of UQFF calibration constants ($\kappa = 5.0 \times 10^{-4} \text{ day}^{-1}$, $[\text{SSq}] = 0.57$) uniquely enabling this analysis by establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. Background: UQFF Propagation Across Cosmological Distances

In GR, gravitational wave strain scales as $h \propto D_L^{-1}$ (luminosity distance). UQFF adds multiplicative damping:

$$h_{\text{UQFF}}(D_L, z) = F_{\text{combined}}(D_L, z) \times h_{\text{GR}}(D_L)$$

where the combined factor includes:

Aether: $F_{\text{aether}} = \exp(-D_L / d_{\text{aether}}) \approx 1.0$ for $d_{\text{aether}} \gg D_L$

TRZ: $F_{\text{TRZ}} = 1 - f_{\text{TRZ}} = 0.90$

U-m: $F_{\text{Um}} = \exp(-\sigma \times U_m) = \exp(-1.0) \approx 0.6907$

β_m modulation: ~5% oscillatory correction over observation window

$$F_{\text{combined,base}} = F_{\text{TRZ}} \times F_{\text{aether}} \times F_{\text{Um}} = 0.90 \times 1.0 \times 0.6907 = 0.6217$$

2. Simulation Setup: LISA SMBH Merger at $z = 1$

Parameter	Value
Total mass M	$1.00 \times 10^6 M_\odot$

Parameter	Value
Mass ratio q	0.50
Chirp mass M_{chirp}	$4.06 \times 10^6 M_{\odot}$
Redshift z	1.0
Luminosity distance D_L	6.42 Gpc
Observation duration	12 months
Frequency range	1.0 $\rightarrow$ 10.0 mHz
Sample points	2000
GW cycles	212

3. UQFF Modification Factors at $z = 1$

Factor	Symbol	Value	Physical Effect
TRZ suppression	A_{TRZ}	0.90	Vacuum resonance absorption
Aether attenuation	A_{aether}	1.0000	Negligible at 6.42 Gpc
U_m coupling	A_{U_m}	0.6907	Magnetic energy dissipation
Combined base	F_{combined}	0.6217	Net amplitude factor

Modulations over the 12-month observation:

- U_m oscillations: $\sim 10\%$ amplitude at hourly timescale
- β_m drift: $\sim 0.1\%$ over full chirp duration

4. Results

Observable	GR	UQFF
Peak strain h	2.9275×10^{-16}	1.7702×10^{-16}
Strain reduction	—	39.5%
Phase lag at merger	0	0.63 rad = 0.1 cycles
SNR (approximate)	205,910	128,338
SNR ratio UQFF/GR	—	0.62
Residual RMS	—	8.6950×10^{-20}
1-year GW cycles	212	212 (same)

5. Redshift Scaling: $z = 0.5, 1.0, 2.0$

Redshift z	D_L (Gpc)	Amplitude Reduction	Phase Lag
0.5	2.68	32.1%	~ 0.32 rad
1.0	6.42	31.6%	0.63 rad
2.0	17.13	31.6%	~ 1.26 rad

Key finding: UQFF amplitude reduction plateaus at $\sim 32\%$ for $z > 0.5$, confirming that aether attenuation F_{aether} remains near unity out to 17 Gpc. The dominant contributors are F_{TRZ} and F_{U_m} , both

distance-independent.

6. Phase Lag Accumulation

The phase lag accumulates from TRZ energy withdrawal throughout the inspiral:

$$\varphi_{\text{lag}}(t) = 2\pi \times f_{\text{TRZ}} \times \frac{t}{\tau_{\text{merge}}}$$

$$h_{\text{UQFF}}(D_L, z) = F_{\text{combined}}(D_L, z) \times h_{\text{GR}}(D_L), \quad F_{\text{combined}} = 6.217 \times 10^{-1}$$

$$h_{\text{GR,peak}} = 2.9275 \times 10^{-19} \text{ strain}, \quad h_{\text{UQFF,peak}} = 1.7702 \times 10^{-19} \text{ strain}$$

Key numerical results: $DL = 6.42e0 \text{ Gpc}$, $F_{\text{combined}} = 6.217e-1$, $h_{\text{GR}} = 2.9275e-19 \text{ strain}$, $h_{\text{UQFF}} = 1.7702e-19 \text{ strain}$, $\phi_{\text{lag}} = 6.3e-1 \text{ rad}$

$$\phi_{\text{lag}}(t) = 2\pi \times f_{\text{TRZ}} \times t / \tau_{\text{merge}}$$

At $t = 0$: $\phi_{\text{lag}} = 0 \text{ rad}$

At $t = 6 \text{ months}$: $\phi_{\text{lag}} = 0.31 \text{ rad}$

At $t = 12 \text{ months}$: $\phi_{\text{lag}} = \mathbf{0.63 \text{ rad} = 0.10 \text{ cycles}}$

This 0.1-cycle residual is measurable with LISA's precision timing (phase sensitivity $< 0.01 \text{ cycle}$ at $\text{SNR} > 100,000$).

7. LISA Detectability

Metric	Value	LISA Threshold
SNR_UQFF	128,338	> 5 ■
Phase lag	0.63 rad	Detectable at LISA sensitivity ■
Amplitude modulation	$\sim 10\%$ (hourly)	Visible in 12-month dataset ■
Strain floor comparison	$h_{\text{UQFF}} = 1.77 \times 10^{-1}$ ■	Well above LISA noise floor ■

8. Observational Signatures for UQFF Identification

Systematic amplitude deficit: UQFF predicts $\sim 40\%$ less strain than GR templates; persistent across all SMBH masses

Phase lag signature: 0.1-cycle lag at merger provides a smoking-gun residual in GR-template matched filtering

Hourly amplitude modulations: U_m oscillations create $\sim 10\%$ amplitude drift visible in the time-domain LISA data stream

Distance-independent reduction: Flat 32% reduction from $z = 0.5$ to 2.0 distinguishes UQFF from astrophysical effects

9. Conclusion

UQFF predicts a ~40% strain reduction and 0.1-cycle phase lag for a $10^6 M_\odot$ SMBH merger at $z = 1$ observed by LISA over 12 months. The amplitude reduction is nearly distance-independent at 31–32% across $z = 0.5\text{--}2.0$, dominated by TRZ and U_m coupling. With $\text{SNR} \approx 128,000$, both the amplitude and phase signatures are robustly detectable by LISA, providing a definitive test of UQFF vs GR in the mHz band.

Appendix: UQFF Production Framework Reference (v4.75+)

Added by `upgradeearlywhitepapers.py` (v4.75). This appendix cross-references the production physics constants and master equations to enable reproducibility against the current codebase state.

A.1 Calibration Constants

Symbol	Value	Description
κ	$5.0 \times 10^{-11} \text{ day}^{-1}$	UQFF exponential decay rate
[SSq]	0.57	Universal Quantized Factor
β_i	0.60–0.61	Buoyancy coupling coefficient
k_1	1.5	Ug1 DPM-dipole coupling
k_2	1.2	Ug2 outer-bubble charge coupling
k_3	1.8	Ug3 string-rotation coupling
k_4	2.0	Ug4 vacuum-concentration coupling
η	10^{-22}	Inertia tensor scale
$E_{\text{react}}(0)$	10^{54} J	Reference reactive energy

A.2 F_U Master Equation (Complete — 4 terms)

$$F_U = U_{\{g1\}} + U_{\{g2\}} + U_{\{g3\}} + U_{\{g4\}} + U_{\{bi\}} + U_m - \sum_{i=1}^4 k_i \text{igl}[\lambda_i \cdot U_i(r,t) \cdot E_{\text{react}}] \text{igr}$$

Term	Description	Implementation
Ug1	DPM magnetic dipole	<code>compute_Ug1_SOURCE4 / compute_Ug1()</code>
Ug2	Outer-field bubble (charge-reactivity)	<code>compute_Ug2_SOURCE4 / compute_Ug2()</code>
Ug3	Magnetic string rotation	<code>compute_Ug3_SOURCE4 / compute_Ug3()</code>
Ug4	Vacuum concentration (star-BH)	<code>compute_Ug4_SOURCE4 / compute_Ug4()</code>
Ubi	Buoyancy force	<code>compute_Ubi_SOURCE4 / compute_Ubi()</code>

Term	Description	Implementation
Um	Universal Magnetism (Heaviside-amplified)	compute_Um_SOURCE4 / compute_Um()
$-\Sigma \lambda_{\text{H}} \cdot \mathbf{U} \cdot \mathbf{E}_{\text{react}}$	4th dissipation term (PAPER_420)	compute_FU_SOURCE4 / full pipeline

4th dissipation term parameters (PAPER_420): $\lambda_{\text{H}}=10^{-10}$, $\lambda_{\text{H}}=10^{-12}$, $\lambda_{\text{H}}=10^{-11}$, $\lambda_{\text{H}}=10^{-13}$ (free parameters, not yet empirically calibrated)

A.3 Um Heaviside Phase-Transition Amplifier (PAPER_421)

```
U_m^{\mathrm{full}} = U_m^{\mathrm{base}} \times \mathrm{sigl}(1 + 10^{13} \backslash, \backslash \Theta(\mathrm{ho}_{\mathrm{SCm}} - \mathrm{ho}_{\mathrm{c}}) \mathrm{igr}) \times \mathrm{sigl}(1 + A_{\mathrm{q}} \cos(\Delta \omega t) \mathrm{igr})
```

Symbol	Value	Description
ρ_{c}	10^{14} kg/m^3	SCm critical superconducting density
A_{q}	0.1	Quasi-periodic beating amplitude (10%)
$\Delta \omega$	$2\pi/(434 \cdot 365.25) \text{ rad/day}$	434-year Gleisberg supercycle

A.4 UQFF Four Operational Modes

Mode	Dominant Term	Primary Use Case
Compressed	$U_{\text{g_sum}}$ + Newtonian base	Isolated stellar/BH systems
Resonant	5 resonance frequencies (aDPM, aTHz, ...)	Multi-scale field interactions
Buoyant	$\beta_{\text{i}} \times U_{\text{bi}}$	Expanding nebulae, stellar winds
Superconductive	$U_{\text{m}} \times (1 + 10^{13} \cdot f_{\text{H}})$	Magnetars, SCm critical-density regime

Implementation status: all 4 modes operational in MAIN_1_CoAnQi.cpp, CondensedPhysics.py, and CondensedPhysics2.py.
