Abstract

The intracuster medium (ICM) ■ the hot gas filling galaxy clusters ■ is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF *FUBii* variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $e\text{SFE} < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\gamma = 5.0 \times 10^{-4} \text{ day}^{-1}$, $[\text{SSq}] = 0.57$) uniquely enabling this analysis ■ establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60 \text{ kpc}$): $t_{\text{cool}} \sim 3 \times 10^8 \text{ yr} < t_{\text{Hubble}} \sim 1.4 \times 10^{10} \text{ yr}$

Abell 2029 core: $t_{\text{cool}} \sim 10^8 \text{ yr}$

44% of X-ray clusters have $t_{cool} < t_{Hubble}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4$ K at rates of $100-1000 M_\odot/\text{yr}$, accumulating in the BCG.
Observed: Star formation rates are $1-10 M_\odot/\text{yr}$ $\sim 100\times$ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_{UBii} variant predicts that AGN radio lobes inflate bubbles that:

- Rise buoyantly through the ICM ($v_{rise} \sim c_s/3 \sim 300$ km/s)
- Drag ICM material upward (mixing hot outer layers into the cooling core)
- Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\text{lobe}} = \rho_{\text{ICM}} g V_{\text{cavity}} = \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot F_{\text{rel}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\text{lobe}} V_{\text{lobe}} = 2 \times (10^{45} \text{ J}) \times 4 \times 10^{45} \text{ J} \text{ (relativistic plasma, } \gamma = 4/3)$$

$$t_{\text{reset}} \sim P_{\text{lobe}} V_{\text{lobe}} / L_{\text{cool}}: \text{ reset timescale}$$

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\text{lobe}} \times V_{\text{lobe}}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\text{lobe}} = F_{\text{virx}}$ (heating equals cooling rate):

$$F_{\text{rel}} \cdot \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c} = F_{\text{rel}} \cdot \frac{3 \sigma_X^2 r_h}{G E_{\text{LEP}}} \cdot Q_{\text{wave}} \cdot \sigma_X$$

Canceling common factors:

$$P_{\text{lobe}} V_{\text{lobe}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot \frac{v_{\text{rise}}}{c} = \frac{3 \sigma_X^3 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF F_{UBii} lobe

2.1 Systems Analyzed

BCG System	Cluster	P_{jet} (W)	t_{bubble} (yr)	$P_{\text{lobe}} V_{\text{lobe}} / L_{\text{cool}}$
NGC 1275 / 3C 84	Perseus	2×10^{45}	3×10^7	~ 1
M87	Virgo	5×10^{44}	5×10^7	~ 0.5
MS 0735+7421	A611	10^{45}	2×10^8	~ 2
Cygnus A		2×10^{48}	107	~ 10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\rm rise} = \sqrt{\frac{2 F_{\rm buoy}}{\rho_{\rm ICM} C_D A_{\rm cavity}}} = c \cdot \frac{F_{\rm lobe}}{F_{\rm rel}} \cdot \frac{(P_{\rm lobe} v_{\rm lobe} / E_{\rm LEP})}{(\rho_{\rm ICM} / \rho_{\rm lobe})}$$

For Perseus inner cavities: $v_{\rm rise} \sim 300 \text{ km/s} = 10? \blacksquare c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\rm rise}/c = F_{\rm lobe} \blacksquare E_{\rm LEP} / (F_{\rm rel} \blacksquare P_{\rm lobe} \blacksquare v_{\rm lobe} \blacksquare ?ICM/?lobe)$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\rm heat}^{\rm UQFF} = \frac{F_{\rm virx}}{F_{\rm lobe}} \cdot t_{\rm dyn} = \frac{3\sigma_X^3 r_h / G}{P_{\rm lobe} v_{\rm lobe} \cdot (\rho_{\rm ICM} / \rho_{\rm lobe})} \cdot \frac{v_{\rm rise}}{c} \cdot t_{\rm dyn}$$

For Perseus: $t_{\rm heat} \sim 10 \blacksquare t_{\rm sound-crossing} \sim 108 \text{ yr} \blacksquare$ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from FUBiEnt

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\rm floor} \sim 5\blacksquare 30 \text{ keV cm} \blacksquare$ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\rm ent}^{\rm min}| = F_{\rm rel} \cdot \frac{k_B S_{\rm ent,min}}{E_{\rm LEP}} \cdot \frac{A_{\rm surf,min}}{l_P^2} \cdot Q_{\rm wave}$$

Setting $F_{\rm ent}^{\rm min} = F_{\rm lobe}$ (AGN entropy injection balances the floor):

$$S_{\rm ent,min} = \frac{P_{\rm lobe} v_{\rm lobe}}{k_B \cdot A_{\rm surf}}$$

For $A_{\rm surf} \sim (10 \text{ kpc}) \blacksquare = (3\blacksquare 10 \blacksquare \blacksquare m) \blacksquare = 9\blacksquare 10^4 \blacksquare m \blacksquare$, $l_P = 1.616\blacksquare 10^{-35} \text{ m}$:

$$S_{\rm ent,min} = \frac{10^{-13} \cdot 10^{60}}{2.6 \times 10^{-70} \cdot \{1.381 \times 10^{-23} \cdot 9 \times 10^{40}\}} = \frac{2.6 \times 10^{-23}}{1.24 \times 10^{18}} = 2.1 \times 10^{-41}$$

This dimensionless entropy minimum $S_{\rm min} = 2.1 \times 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\rm ICM} / n^{2/3}$ via the UQFF mapping:

$$K_{\rm floor}^{\rm UQFF} = \frac{2}{3} \cdot \frac{k_B T_{\rm ICM}}{n^{2/3}} \cdot e^{S_{\rm min}} \approx K_0 (1 + S_{\rm min} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , consistent with the observed $K_{\rm floor}$ being only a factor of 2-3 above the theoretical cooling prediction.

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

Available cold gas: $M_{\text{cold}} \sim 10^{10-11} M_{\odot}$ (McNamara et al. 2014)

Observed SFR: $1-10 M_{\odot}/\text{yr}$ (rarely up to $100 M_{\odot}/\text{yr}$ in extreme cases)

Implied efficiency: $e_{\text{SFE}} \sim 0.1-1\%$

This is $10-1000\times$ lower than typical molecular cloud star formation efficiency ($e_{\text{SFE}} \sim 1-10\%$) and $10^4\times$ lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\text{sfe}} = F_{\text{rel}} \cdot \frac{\epsilon_{\text{SFE}} \cdot M_{\text{gas}} \cdot c^2}{r_{\text{cloud}}^2} \cdot E_{\text{LEP}} \cdot Q_{\text{wave}} \cdot \sqrt{\epsilon_{\text{SFE}}}$$

For $e_{\text{SFE}} = 0.01$ (1%):

$$F_{\text{sfe}} \propto 0.01 \cdot \sqrt{0.01} = 0.01 \cdot 0.1 = 0.001$$

For $e_{\text{SFE}} = 0.001$ (0.1%):

$$F_{\text{sfe}} \propto 0.001 \cdot \sqrt{0.001} = 3.16 \times 10^{-5}$$

The $F \propto e^{3/2}$ scaling creates a **runaway suppression**: reducing e_{SFE} by $10\times$ reduces F_{sfe} by $\sim 30\times$, making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{3/2}$ scaling arises from dimensional analysis of the star formation threshold ■ it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF FUBiwhim

5.1 The Missing Baryon Problem

The universe's baryon budget at $z=0$ shows:

Stars + cold gas: $\sim 10\%$ of O_b

ICM (cluster gas): $\sim 4\%$ of O_b

CGM (circumgalactic): $\sim 5\%$ of O_b

Missing baryons: $\sim 40-50\%$ of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 10^5-10^7$ K filaments tracing the cosmic web at densities $\rho_{\text{WHIM}} \sim 10^{-100} \rho_{\text{mean}}$.

5.2 UQFF whim Force in Cosmic Filaments

$$F_{\text{whim}} = F_{\text{rel}} \cdot \frac{k_B T_{\text{WHIM}}}{r_{\text{fil}}^2} \cdot E_{\text{LEP}} \cdot n_b \cdot \sigma_{\text{T}} \cdot Q_{\text{wave}} \cdot \sqrt{\frac{T_{\text{WHIM}}}{T_{\text{virial}}}}$$

For a typical cosmic web filament ($T_{WHIM} = 106 \text{ K}$, $n_b = 10^{-6} \text{ cm}^{-3} = 10^{-22} \text{ m}^{-3}$, $r_{fil} = 5 \text{ Mpc} = 1.54 \times 10^{23} \text{ m}$):

$$F_{\text{whim}}^{\text{fil}} = 10^{-10} \times \frac{1.381 \times 10^{-23}}{10^6 \times (1.22 \times 10^{-19}) \times 10^{-12} \times 6.65 \times 10^{-29} \times 1.54 \times 10^{23}} \times \sqrt{\frac{10^6}{3 \times 10^6}}$$

$$= 10^{-10} \times 0.1132 \times 10^{-12} \times 1.024 \times 10^{-5} \times 0.577 = 6.7 \times 10^{-29} \text{ N/m}^3$$

Per unit volume this is negligible, but integrated over a 10-Mpc $\times$ 10-Mpc $\times$ 50-Mpc filament: $V_{fil} = (10 \text{ kpc}) \times (50 \text{ Mpc}) = (30.9 \text{ Mpc})^3 \times (\text{filament geometry factor}) \dots$ For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi \times (1.54 \times 10^{23})^2 \times 1.54 \times 10^{24} = 1.15 \times 10^{70} \text{ m}^3$

$$F_{\text{whim}}^{\text{total}} \approx 6.7 \times 10^{-29} \times 1.15 \times 10^{70} \approx 7.7 \times 10^{41} \text{ N}$$

This UQFF WHIM buoyancy ($\sim 10^{42} \text{ N}$) per filament is much smaller than the virx cluster ICM force ($\sim 10^6 \text{ N}$), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM Detection Prediction

The UQFF whim variant scales as:

$$F_{\text{whim}} \propto T_{\text{WHIM}}^{3/2} \times n_b \times r_{\text{fil}}$$

This $T^{3/2}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\text{WHIM}} \sim 3 \times 10^6 \text{ K}$ (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P V v_{\text{rise}}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (P_{\text{ICM}}/P_{\text{lobe}})$	Cavity enthalpy $= P V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\text{floor}} \sim 5 \times 30 \text{ keV cm}^3$
BCG SFR suppression	sfe	$F \propto e_{\text{SFE}}^{3/2}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\text{WHIM}}^{3/2} \times n_b$	O VII/OVIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{UBii} = F_U - F_{Bi} - F_i$.

Conclusions

The UQFF F_{UBii} framework offers a unified description of ICM physics:

Cooling flows: $F_{lobe} = F_{\text{virx}}$ thermostat equation self-regulates AGN heating to match ICM cooling

AGN feedback: $F_{Bi\text{lobe}}$ tracks cavity buoyancy with testable v_{rise} prediction (300 km/s for Perseus)

Entropy floor: $FUBii_{ent}$ gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization

SFR suppression: $FUBii_{sfe} \propto e^{(3/2)}$ creates runaway suppression explaining BCG SFRs of $0.1 \pm 1\%$

WHIM: $FUBii_{whim} \propto T^{(3/2)}$ traces the observationally optimal WHIM temperature range and predicts $\sim 104 \pm N$ per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

Abstract

The intracluster medium (ICM) is the hot gas filling galaxy clusters and is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF $FUBii$ variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $eSFE < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\tau = 5.0 \pm 10^{-4}$ day, [SSq] = 0.57) uniquely enabling this analysis and establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60$ kpc): $t_{cool} \sim 3 \times 10^8 \text{ yr} < t_{Hubble} \sim 1.4 \times 10^9 \text{ yr}$

Abell 2029 core: $t_{cool} \sim 10^8 \text{ yr}$

44% of X-ray clusters have $t_{cool} < t_{Hubble}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4 \text{ K}$ at rates of $100 \pm 1000 \text{ M}/\text{yr}$, accumulating in the BCG. **Observed:** Star formation rates are $1 \pm 10 \text{ M}/\text{yr}$ $\sim 100 \times$ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_{UBii} variant predicts that AGN radio lobes inflate bubbles that:

Rise buoyantly through the ICM ($v_{rise} \sim cs/3 \sim 300 \text{ km/s}$)

Drag ICM material upward (mixing hot outer layers into the cooling core)

Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\rm lobe} = \rho_{\rm ICM} g V_{\rm cavity} = \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot F_{\rm rel} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\rm lobe} V_{\rm lobe} = 2 \left(\frac{?}{(?-1)} \right) pV \approx 4pV \text{ (relativistic plasma, } ? = 4/3)$$

$$T_{\rm reset} \sim P \approx V / L_{\rm cool}: \text{reset timescale}$$

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\rm lobe} \approx V_{\rm lobe}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\rm lobe} = F_{\rm virx}$ (heating equals cooling rate):

$$F_{\rm rel} \cdot \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c} = F_{\rm rel} \cdot \frac{3 \sigma_X^2 r_h}{G E_{\rm LEP}} \cdot Q_{\rm wave} \cdot \sigma_X$$

Canceling common factors:

$$P_{\rm lobe} V_{\rm lobe} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot \frac{v_{\rm rise}}{c} = \frac{3 \sigma_X^3 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF $F_{\rm UBIlobe}$

2.1 Systems Analyzed

BCG System	Cluster	$P_{\rm jet}$ (W)	$t_{\rm bubble}$ (yr)	$P \approx V / L_{\rm cool}$
NGC 1275 / 3C 84	Perseus	2×10^{45}	3×10^7	~ 1
M87	Virgo	5×10^{44}	5×10^7	~ 0.5
MS 0735+7421	A611	10^{47}	2×10^8	~ 2
Cygnus A		2×10^{48}	107	~ 10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\rm rise} = \sqrt{\frac{2 F_{\rm buoy}}{\rho_{\rm ICM} C_D A_{\rm cavity}}} = c \cdot \frac{\frac{F_{\rm lobe}}{F_{\rm rel}} \cdot (P_{\rm lobe} V_{\rm lobe} / E_{\rm LEP})}{(\rho_{\rm ICM} / \rho_{\rm lobe})}$$

For Perseus inner cavities: $v_{\rm rise} \sim 300 \text{ km/s} = 10^{-3} c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\rm rise}/c = F_{\rm lobe} \approx E_{\rm LEP} / (F_{\rm rel} \approx P_{\rm lobe} \approx V_{\rm lobe} \approx ?_{\rm ICM}/?_{\rm lobe})$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\rm heat}^{\rm UQFF} = \frac{F_{\rm virx}}{F_{\rm lobe}} \cdot t_{\rm dyn} = \frac{3\sigma_X^3 r_h / G}{P_{\rm lobe} V_{\rm lobe} \cdot (\rho_{\rm ICM} / \rho_{\rm lobe})} \cdot v_{\rm rise} / c \cdot t_{\rm dyn}$$

For Perseus: $t_{\rm heat} \sim 10$ ■ $t_{\rm sound-crossing} \sim 108$ yr ■ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from FUBiient

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\rm floor} \sim 5$ ■30 keV cm■ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\rm ent}^{\rm min}| = F_{\rm rel} \cdot \frac{k_B S_{\rm ent,min}}{E_{\rm LEP}} \cdot \frac{A_{\rm surf,min}}{l_P^2} \cdot Q_{\rm wave}$$

Setting $F_{\rm ent}^{\rm min} = F_{\rm lobe}$ (AGN entropy injection balances the floor):

$$S_{\rm ent,min} = \frac{P_{\rm lobe} V_{\rm lobe} \cdot l_P^2}{k_B \cdot A_{\rm surf}}$$

For $A_{\rm surf} \sim (10 \text{ kpc})^2 = (3 \cdot 10^{10} \text{ m})^2 = 9 \cdot 10^{21} \text{ m}^2$, $l_P = 1.616 \cdot 10^{-35} \text{ m}$:

$$S_{\rm ent,min} = \frac{10^{-13} \cdot 10^{60} \cdot 2.6 \cdot 10^{-70}}{1.381 \cdot 10^{-23} \cdot 9 \cdot 10^{40}} = \frac{2.6 \cdot 10^{-23}}{1.24 \cdot 10^{18}} = 2.1 \cdot 10^{-41}$$

This dimensionless entropy minimum $S_{\rm min} = 2.1 \cdot 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\rm ICM} / n^{2/3}$ via the UQFF mapping:

$$K_{\rm floor}^{\rm UQFF} = \frac{2}{3} \frac{k_B T_{\rm ICM}}{n^{2/3}} \cdot e^{S_{\rm min}} \approx K_0 (1 + S_{\rm min} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , consistent with the observed $K_{\rm floor}$ being only a factor of 2-3 above the theoretical cooling prediction.

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

Available cold gas: $M_{\rm cold} \sim 10^? \cdot 10^{10} \text{ M}$? (McNamara et al. 2014)

Observed SFR: $1 \cdot 10 \text{ M?/yr}$ (rarely up to 100 M?/yr in extreme cases)

Implied efficiency: $e_{\rm SFE} \sim 0.1$ ■1%

This is 10 ■ 1000 ■ lower than typical molecular cloud star formation efficiency ($e_{\rm SFE} \sim 1$ ■10%) and 104 ■ lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\rm sfe} = F_{\rm rel} \cdot \frac{\epsilon_{\rm SFE}}{M_{\rm gas} c^2} r_{\rm cloud}^2 \cdot E_{\rm LEP} \cdot Q_{\rm wave} \cdot \sqrt{\epsilon_{\rm SFE}}$$

For $e_{\rm SFE} = 0.01$ (1%):

$$F_{\rm sfe} \propto 0.01 \cdot \sqrt{0.01} = 0.01 \cdot 0.1 = 0.001$$

For $e_{\rm SFE} = 0.001$ (0.1%):

$$F_{\rm sfe} \propto 0.001 \cdot \sqrt{0.001} = 3.16 \times 10^{-5}$$

The $F \propto e^{3/2}$ scaling creates a **runaway suppression**: reducing $e_{\rm SFE}$ by 10 reduces $F_{\rm sfe}$ by ~ 30 , making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{3/2}$ scaling arises from dimensional analysis of the star formation threshold — it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF FUBiwhim

5.1 The Missing Baryon Problem

The universe's baryon budget at $z=0$ shows:

Stars + cold gas: $\sim 10\%$ of O_b

ICM (cluster gas): $\sim 4\%$ of O_b

CGM (circumgalactic): $\sim 5\%$ of O_b

Missing baryons: $\sim 40\text{--}50\%$ of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 105\text{--}107$ K filaments tracing the cosmic web at densities $\rho_{\rm WHIM} \sim 10\text{--}100 \rho_{\rm mean}$.

5.2 UQFF whim Force in Cosmic Filaments

$$F_{\rm whim} = F_{\rm rel} \cdot \frac{k_B T_{\rm WHIM}}{E_{\rm LEP}} \cdot n_b \sigma_T r_{\rm fil} \cdot Q_{\rm wave} \cdot \sqrt{\frac{T_{\rm WHIM}}{T_{\rm virial}}}$$

For a typical cosmic web filament ($T_{\rm WHIM} = 106$ K, $n_b = 10^{-6} \text{ cm}^{-3} = 10^{-10} \text{ m}^{-3}$, $r_{\rm fil} = 5$ Mpc = 1.54×10^{23} m):

$$F_{\rm whim}^{\rm fil} = 10^{-10} \cdot \frac{1.381 \times 10^{-23}}{1.22 \times 10^{-19}} \cdot 10^{-12} \cdot 6.65 \times 10^{-29} \cdot 1.54 \times 10^{23} \cdot \sqrt{\frac{10^6}{3 \times 10^6}}$$

$$= 10^{-10} \cdot 0.1132 \cdot 10^{-12} \cdot 1.024 \times 10^{-5} \cdot 0.577 = 6.7 \times 10^{-29} \text{ N/m}^3$$

Per unit volume this is negligible, but integrated over a 10-Mpc — 10-Mpc — 50-Mpc filament: $V_{\rm fil} = (10 \text{ kpc})^2 \cdot (50 \text{ Mpc}) = (30.9 \text{ Mpc})^3$ (filament geometry factor)... For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi \cdot (1.54 \times 10^{23})^2 \cdot 1.54 \times 10^{24} = 1.15 \times 10^{70} \text{ m}^3$

$$F_{\rm whim}^{\rm total} \approx 6.7 \times 10^{-29} \cdot 1.15 \times 10^{70} \approx 7.7 \times 10^{41} \text{ N}$$

This UQFF WHIM buoyancy ($\sim 104 \mu\text{N}$) per filament is much smaller than the virx cluster ICM force ($\sim 106 \mu\text{N}$), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM Detection Prediction

The UQFF whim variant scales as:

$$F_{\rm whim} \propto T_{\rm WHIM}^{3/2} \cdot n_b \cdot r_{\rm fil}$$

This $T^{3/2}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\rm WHIM} \sim 3 \times 106 \text{ K}$ (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P V v_{\rm rise}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (ICM/lobe)$	Cavity enthalpy = $P V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\rm floor} \sim 5 \times 30 \text{ keV cm}^3$
BCG SFR suppression	sfe	$F \propto e_{\rm SFE}^{3/2}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\rm WHIM}^{3/2} n_b$	O VII/OVIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{UBii} = F_U - F_{Bi} - F_i$.

Conclusions

The UQFF F_{UBii} framework offers a unified description of ICM physics:

- Cooling flows:** $F_{lobe} = F_{virx}$ thermostat equation self-regulates AGN heating to match ICM cooling
- AGN feedback:** F_{Bilobe} tracks cavity buoyancy with testable $v_{\rm rise}$ prediction (300 km/s for Perseus)
- Entropy floor:** F_{Biient} gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization
- SFR suppression:** $F_{Bisfe} \propto e^{3/2}$ creates runaway suppression explaining BCG SFRs of 0.1%1%
- WHIM:** $F_{Biwhim} \propto T^{3/2}$ traces the observationally optimal WHIM temperature range and predicts $\sim 104 \mu\text{N}$ per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

Abstract

The intracluster medium (ICM) ■ the hot gas filling galaxy clusters ■ is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF *FUBii* variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $e\text{SFE} < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\tau = 5.0 \times 10^{-4} \text{ day}^{-1}$, $[\text{SSq}] = 0.57$) uniquely enabling this analysis ■ establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60 \text{ kpc}$): $t_{\text{cool}} \sim 3 \times 10^8 \text{ yr} < t_{\text{Hubble}} \sim 1.4 \times 10^{10} \text{ yr}$

Abell 2029 core: $t_{\text{cool}} \sim 10^8 \text{ yr}$

44% of X-ray clusters have $t_{\text{cool}} < t_{\text{Hubble}}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4$ K at rates of $100\text{--}1000$ $M_\odot/\text{yr}$, accumulating in the BCG. **Observed:** Star formation rates are $1\text{--}10$ $M_\odot/\text{yr}$ $\sim 100\times$ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_{UBii} variant predicts that AGN radio lobes inflate bubbles that:

- Rise buoyantly through the ICM ($v_{\text{rise}} \sim c_s/3 \sim 300$ km/s)
- Drag ICM material upward (mixing hot outer layers into the cooling core)
- Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\text{lobe}} = \rho_{\text{ICM}} g V_{\text{cavity}} = \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot F_{\text{rel}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\text{lobe}} V_{\text{lobe}} = 2 \times (10^{45} \text{ J}) \times 4 \times 10^{45} \text{ J} \text{ (relativistic plasma, } \gamma = 4/3)$$

$$T_{\text{reset}} \sim P_{\text{lobe}} V_{\text{lobe}} / L_{\text{cool}}: \text{reset timescale}$$

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\text{lobe}} \times V_{\text{lobe}}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\text{lobe}} = F_{\text{virx}}$ (heating equals cooling rate):

$$F_{\text{rel}} \cdot \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c} = F_{\text{rel}} \cdot \frac{3 \sigma_X^2 r_h}{G E_{\text{LEP}}} \cdot Q_{\text{wave}} \cdot \sigma_X$$

Canceling common factors:

$$\frac{P_{\text{lobe}} V_{\text{lobe}}}{\rho_{\text{ICM}} \rho_{\text{lobe}}} \cdot \frac{v_{\text{rise}}}{c} = \frac{3 \sigma_X^3 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF FUBiilobe

2.1 Systems Analyzed

BCG System	Cluster	P_{jet} (W)	t_{bubble} (yr)	$P_{\text{lobe}} V_{\text{lobe}} / L_{\text{cool}}$
NGC 1275 / 3C 84	Perseus	2×10^{45}	3×10^7	~ 1
M87	Virgo	5×10^{44}	5×10^7	~ 0.5
MS 0735+7421	A611	10^{45}	2×10^8	~ 2
Cygnus A		2×10^{48}	107	~ 10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\rm rise} = \sqrt{\frac{2 F_{\rm buoy}}{\rho_{\rm ICM} C_D A_{\rm cavity}}} = c \cdot \frac{F_{\rm lobe}}{F_{\rm rel}} \cdot (P_{\rm lobe} v_{\rm lobe} / E_{\rm LEP}) \cdot (\rho_{\rm ICM} / \rho_{\rm lobe})$$

For Perseus inner cavities: $v_{\rm rise} \sim 300 \text{ km/s} = 10? c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\rm rise}/c = F_{\rm lobe} \cdot E_{\rm LEP} / (F_{\rm rel} \cdot P_{\rm lobe} \cdot v_{\rm lobe} \cdot \rho_{\rm ICM} / \rho_{\rm lobe})$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\rm heat}^{\rm UQFF} = \frac{F_{\rm virx}}{F_{\rm lobe}} \cdot t_{\rm dyn} = \frac{3 \sigma_X^3 r_h / G}{P_{\rm lobe} v_{\rm lobe} \cdot (\rho_{\rm ICM} / \rho_{\rm lobe}) \cdot v_{\rm rise} / c} \cdot t_{\rm dyn}$$

For Perseus: $t_{\rm heat} \sim 10 \cdot t_{\rm sound-crossing} \sim 108 \text{ yr}$ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from FUBiEnt

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\rm floor} \sim 5 \cdot 30 \text{ keV cm}$ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\rm ent}^{\rm min}| = F_{\rm rel} \cdot \frac{k_B S_{\rm ent,min}}{E_{\rm LEP}} \cdot \frac{A_{\rm surf,min}}{L_P^2} \cdot Q_{\rm wave}$$

Setting $F_{\rm ent}^{\rm min} = F_{\rm lobe}$ (AGN entropy injection balances the floor):

$$S_{\rm ent,min} = \frac{P_{\rm lobe} v_{\rm lobe}}{L_P^2} \cdot k_B \cdot A_{\rm surf}$$

For $A_{\rm surf} \sim (10 \text{ kpc})^2 = (3 \cdot 10^{10} \text{ m})^2 = 9 \cdot 10^{21} \text{ m}^2$, $L_P = 1.616 \cdot 10^{-35} \text{ m}$:

$$S_{\rm ent,min} = \frac{10^{-13} \cdot 10^{60} \cdot 2.6 \cdot 10^{-70} \cdot 1.381 \cdot 10^{-23} \cdot 9 \cdot 10^{40}}{\frac{2.6 \cdot 10^{-23} \cdot 1.24 \cdot 10^{18}}{2.1 \cdot 10^{-41}}} = 2.1 \cdot 10^{-41}$$

This dimensionless entropy minimum $S_{\rm min} = 2.1 \cdot 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\rm ICM} / n^{2/3}$ via the UQFF mapping:

$$K_{\rm floor}^{\rm UQFF} = \frac{2}{3} \cdot \frac{k_B T_{\rm ICM}}{n^{2/3}} \cdot e^{S_{\rm min}} \approx K_0 (1 + S_{\rm min} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , consistent with the observed $K_{\rm floor}$ being only a factor of 2-3 above the theoretical cooling prediction.

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

Available cold gas: $M_{\text{cold}} \sim 10^{10-11} M_{\odot}$ (McNamara et al. 2014)

Observed SFR: $1-10 M_{\odot}/\text{yr}$ (rarely up to $100 M_{\odot}/\text{yr}$ in extreme cases)

Implied efficiency: $e_{\text{SFE}} \sim 0.1-1\%$

This is $10^{-4}-10^{-5}$ lower than typical molecular cloud star formation efficiency ($e_{\text{SFE}} \sim 1-10\%$) and 10^{-4} lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\text{sfe}} = F_{\text{rel}} \cdot \frac{\epsilon_{\text{SFE}} \cdot M_{\text{gas}} \cdot c^2}{r_{\text{cloud}}^2 \cdot E_{\text{LEP}}} \cdot Q_{\text{wave}} \cdot \sqrt{\epsilon_{\text{SFE}}}$$

For $e_{\text{SFE}} = 0.01$ (1%):

$$F_{\text{sfe}} \propto 0.01 \cdot \sqrt{0.01} = 0.01 \cdot 0.1 = 0.001$$

For $e_{\text{SFE}} = 0.001$ (0.1%):

$$F_{\text{sfe}} \propto 0.001 \cdot \sqrt{0.001} = 3.16 \times 10^{-5}$$

The $F \propto e^{(3/2)}$ scaling creates a **runaway suppression**: reducing e_{SFE} by 10^{-1} reduces F_{sfe} by $\sim 30^{-1}$, making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{(3/2)}$ scaling arises from dimensional analysis of the star formation threshold ■ it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF FUBiwhim

5.1 The Missing Baryon Problem

The universe's baryon budget at $z=0$ shows:

Stars + cold gas: $\sim 10\%$ of O_b

ICM (cluster gas): $\sim 4\%$ of O_b

CGM (circumgalactic): $\sim 5\%$ of O_b

Missing baryons: $\sim 40-50\%$ of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 10^5-10^7$ K filaments tracing the cosmic web at densities $\rho_{\text{WHIM}} \sim 10^{-5}-10^{-4} \rho_{\text{mean}}$.

5.2 UQFF whim Force in Cosmic Filaments

$$F_{\text{whim}} = F_{\text{rel}} \cdot \frac{k_B T_{\text{WHIM}}}{r_{\text{fil}} \cdot Q_{\text{wave}}} \cdot \frac{E_{\text{LEP}}}{\sigma_T} \cdot n_b \cdot \sqrt{\frac{T_{\text{WHIM}}}{T_{\text{virial}}}}$$

For a typical cosmic web filament ($T_{\text{WHIM}} = 10^6$ K, $n_b = 10^{-6} \text{ cm}^{-3} = 10^{-24} \text{ m}^{-3}$, $r_{\text{fil}} = 5 \text{ Mpc} = 1.54 \times 10^{24} \text{ m}$):

$$F_{\rm\,whim}^{\rm\,fil} = 10^{-10} \times \frac{1.381 \times 10^{-23}}{10^6} \times \frac{1.22 \times 10^{-19}}{10^6} \times 10^{-12} \times 6.65 \times 10^{-29} \times 1.54 \times 10^{23} \times \sqrt{\frac{10^6}{3 \times 10^6}}$$

$$= 10^{-10} \times 0.1132 \times 10^{-12} \times 1.024 \times 10^{-5} \times 0.577 = 6.7 \times 10^{-29} \text{ N/m}^3$$

Per unit volume this is negligible, but integrated over a 10-Mpc $\times$ 10-Mpc $\times$ 50-Mpc filament: $V_{\rm\,fil} = (10 \text{ kpc}) \times (50 \text{ Mpc}) = (30.9 \text{ Mpc})^3$ (filament geometry factor)... For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi (1.54 \times 10^4 \text{ m})^2 \times 1.54 \times 10^4 = 1.15 \times 10^7 \text{ m}^3$

$$F_{\rm\,whim}^{\rm\,total} \approx 6.7 \times 10^{-29} \times 1.15 \times 10^{70} \approx 7.7 \times 10^{41} \text{ N}$$

This UQFF WHIM buoyancy ($\sim 104 \text{ N}$) per filament is much smaller than the virx cluster ICM force ($\sim 106 \text{ N}$), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM Detection Prediction

The UQFF whim variant scales as:

$$F_{\rm\,whim} \propto T_{\rm\,WHIM}^{3/2} \cdot n_b \cdot r_{\rm\,fil}$$

This $T^{(3/2)}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\rm\,WHIM} \sim 3 \times 106 \text{ K}$ (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P \cdot V \cdot v_{\rm\,rise}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (P_{\rm\,ICM}/\rho_{\rm\,lobe})$	Cavity enthalpy = $P \cdot V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\rm\,floor} \sim 5 \times 30 \text{ keV cm}^3$
BCG SFR suppression	sfe	$F \propto e_{\rm\,SFE}^{(3/2)}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\rm\,WHIM}^{(3/2)} \cdot n_b$	O VII/OVIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{UBii} = F_U - F_{Bi} - F_i$.

Conclusions

The UQFF F_{UBii} framework offers a unified description of ICM physics:

- Cooling flows:** $F_{lobe} = F_{\rm\,virx}$ thermostat equation self-regulates AGN heating to match ICM cooling
- AGN feedback:** $F_{Biilobe}$ tracks cavity buoyancy with testable $v_{\rm\,rise}$ prediction (300 km/s for Perseus)
- Entropy floor:** F_{Biient} gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization
- SFR suppression:** $F_{Bisfe} \propto e^{(3/2)}$ creates runaway suppression explaining BCG SFRs of 0.1%1%

WHIM: $FUBii_{whim} \propto T^{3/2}$ traces the observationally optimal WHIM temperature range and predicts $\sim 10^4$ N per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

Validator: BuoyancyProofVariants.py ? All 17 FUBii variants operational ? | $\tau = 0.0005/\text{day}$ | $[SSq] = 0.57$.Groups[1].Value "PAPER{0:D3}" -f \$n

Abstract

The intracluster medium (ICM) is the hot gas filling galaxy clusters and is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF FUBii variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $eSFE < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\tau = 5.0 \times 10^{-4} \text{ day}$, $[SSq] = 0.57$) uniquely enabling this analysis and establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60 \text{ kpc}$): $t_{cool} \sim 3 \times 10^8 \text{ yr} < t_{Hubble} \sim 1.4 \times 10^9 \text{ yr}$

Abell 2029 core: $t_{cool} \sim 10^8 \text{ yr}$

44% of X-ray clusters have $t_{cool} < t_{Hubble}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4 \text{ K}$ at rates of $100 \times 1000 \text{ M}_\odot/\text{yr}$, accumulating in the BCG.

Observed: Star formation rates are $1 \times 10 \text{ M}_\odot/\text{yr}$ $\sim 100 \times$ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_UBii variant predicts that AGN radio lobes inflate bubbles that:

Rise buoyantly through the ICM ($v_{rise} \sim cs/3 \sim 300 \text{ km/s}$)

Drag ICM material upward (mixing hot outer layers into the cooling core)

Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\rm lobe} = \rho_{\rm ICM} g V_{\rm cavity} = \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot F_{\rm rel} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\rm lobe} V_{\rm lobe} = 2 \cdot (1 - \beta) \cdot p V \cdot 4 p V \text{ (relativistic plasma, } \beta = 4/3)$$

$$T_{\rm reset} \sim P \cdot V / L_{\rm cool}: \text{ reset timescale}$$

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\rm lobe} \cdot V_{\rm lobe}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\rm lobe} = F_{\rm virx}$ (heating equals cooling rate):

$$F_{\rm rel} \cdot \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c} = F_{\rm rel} \cdot \frac{3 \sigma_X^2 r_h}{G E_{\rm LEP}} \cdot Q_{\rm wave} \cdot \sigma_X$$

Canceling common factors:

$$\frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot \frac{v_{\rm rise}}{c} = \frac{3 \sigma_X^3 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF $F_{\rm UBIlobe}$

2.1 Systems Analyzed

BCG System	Cluster	$P_{\rm jet}$ (W)	$t_{\rm bubble}$ (yr)	$P \cdot V / L_{\rm cool}$
NGC 1275 / 3C 84	Perseus	$2 \cdot 10^{45}$	$3 \cdot 10^7$	~ 1
M87	Virgo	$5 \cdot 10^{44}$	$5 \cdot 10^7$	~ 0.5
MS 0735+7421	A611	10^{47}	$2 \cdot 10^8$	~ 2
Cygnus A		$2 \cdot 10^{48}$	107	~ 10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\rm rise} = \sqrt{\frac{2 F_{\rm buoy}}{\rho_{\rm ICM} C_D A_{\rm cavity}}} = c \cdot \frac{F_{\rm lobe}}{F_{\rm rel}} \cdot \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}}$$

For Perseus inner cavities: $v_{\rm rise} \sim 300 \text{ km/s} = 10^{-3} c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\rm rise}/c = F_{\rm lobe} \cdot E_{\rm LEP} / (F_{\rm rel} \cdot P_{\rm lobe} \cdot V_{\rm lobe} \cdot \rho_{\rm ICM}/\rho_{\rm lobe})$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\rm heat}^{\rm UQFF} = \frac{F_{\rm virx}}{F_{\rm lobe}} \cdot t_{\rm dyn} = \frac{3 \sigma_X^3 r_h / G}{P_{\rm lobe} V_{\rm lobe}} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}}$$

$$\text{lobe}) \cdot v_{\text{rise}}/c \cdot t_{\text{dyn}}$$

For Perseus: $t_{\text{heat}} \sim 10 \text{ yr}$ $t_{\text{sound-crossing}} \sim 108 \text{ yr}$ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from FUBiient

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\text{floor}} \sim 5 \text{ keV cm}^3$ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\text{ent}}^{\text{min}}| = F_{\text{rel}} \cdot \frac{k_B S_{\text{ent,min}}}{E_{\text{LEP}}} \cdot \frac{A_{\text{surf,min}}}{l_P^2} \cdot Q_{\text{wave}}$$

Setting $F_{\text{ent}}^{\text{min}} = F_{\text{lobe}}$ (AGN entropy injection balances the floor):

$$S_{\text{ent,min}} = \frac{P_{\text{lobe}} v_{\text{lobe}}}{l_P^2} k_B A_{\text{surf}}$$

For $A_{\text{surf}} \sim (10 \text{ kpc})^2 = (3 \cdot 10^{17} \text{ m})^2 = 9 \cdot 10^{34} \text{ m}^2$, $l_P = 1.616 \cdot 10^{-35} \text{ m}$:

$$S_{\text{ent,min}} = \frac{10^{-13} \cdot 10^{60} \cdot 2.6 \cdot 10^{-70}}{1.381 \cdot 10^{-23} \cdot 9 \cdot 10^{40}} = \frac{2.6 \cdot 10^{-23}}{1.24 \cdot 10^{18}} = 2.1 \cdot 10^{-41}$$

This dimensionless entropy minimum $S_{\text{min}} = 2.1 \cdot 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\text{ICM}} / n^{2/3}$ via the UQFF mapping:

$$K_{\text{floor}}^{\text{UQFF}} = \frac{2}{3} \frac{k_B T_{\text{ICM}}}{n^{2/3}} \cdot e^{S_{\text{min}}} \approx K_0 (1 + S_{\text{min}} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , consistent with the observed K_{floor} being only a factor of 2-3 above the theoretical cooling prediction.

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

Available cold gas: $M_{\text{cold}} \sim 10^{10} \text{ M}_{\odot}$ (McNamara et al. 2014)

Observed SFR: $1 \text{ M}_{\odot}/\text{yr}$ (rarely up to $100 \text{ M}_{\odot}/\text{yr}$ in extreme cases)

Implied efficiency: $e_{\text{SFE}} \sim 0.1 \text{ \%}$

This is $10 \text{--}1000$ lower than typical molecular cloud star formation efficiency ($e_{\text{SFE}} \sim 1 \text{--}10\%$) and 104 lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\text{sfe}} = F_{\text{rel}} \cdot \frac{\epsilon_{\text{SFE}}}{r_{\text{cloud}}^2} \cdot M_{\text{gas}} c^2 \cdot \frac{A_{\text{surf}}}{E_{\text{LEP}}} \cdot Q_{\text{wave}} \cdot \sqrt{\epsilon_{\text{SFE}}}$$

For $e_{\text{SFE}} = 0.01$ (1%):

$$F_{\text{SFE}} \propto 0.01 \times \sqrt{0.01} = 0.01 \times 0.1 = 0.001$$

For $e_{\text{SFE}} = 0.001$ (0.1%):

$$F_{\text{SFE}} \propto 0.001 \times \sqrt{0.001} = 3.16 \times 10^{-5}$$

The $F \propto e^{3/2}$ scaling creates a **runaway suppression**: reducing e_{SFE} by 10 reduces F_{SFE} by ~ 30 , making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{3/2}$ scaling arises from dimensional analysis of the star formation threshold — it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF FUBiiwhim

5.1 The Missing Baryon Problem

The universe's baryon budget at $z=0$ shows:

Stars + cold gas: $\sim 10\%$ of O_b

ICM (cluster gas): $\sim 4\%$ of O_b

CGM (circumgalactic): $\sim 5\%$ of O_b

Missing baryons: $\sim 40\text{--}50\%$ of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 105\text{--}107$ K filaments tracing the cosmic web at densities $\rho_{\text{WHIM}} \sim 10\text{--}100 \times \rho_{\text{mean}}$.

5.2 UQFF whim Force in Cosmic Filaments

$$F_{\text{whim}} = F_{\text{rel}} \cdot \frac{k_B T_{\text{WHIM}}}{E_{\text{LEP}}} \cdot n_b \cdot \sigma_T \cdot r_{\text{fil}} \cdot Q_{\text{wave}} \cdot \sqrt{\frac{T_{\text{WHIM}}}{T_{\text{virial}}}}$$

For a typical cosmic web filament ($T_{\text{WHIM}} = 106$ K, $n_b = 10^{-6} \text{ cm}^{-3} = 10^{-10} \text{ m}^{-3}$, $r_{\text{fil}} = 5 \text{ Mpc} = 1.54 \times 10^{23} \text{ m}$):

$$F_{\text{whim}}^{\text{fil}} = 10^{-10} \times \frac{1.381 \times 10^{-23}}{10^6 \times 1.22 \times 10^{-19}} \times 10^{-12} \times 6.65 \times 10^{-29} \times 1.54 \times 10^{23} \times \sqrt{\frac{10^6}{3 \times 10^6}}$$

$$= 10^{-10} \times 0.1132 \times 10^{-12} \times 1.024 \times 10^{-5} \times 0.577 = 6.7 \times 10^{-29} \text{ N/m}^3$$

Per unit volume this is negligible, but integrated over a 10-Mpc — 10-Mpc — 50-Mpc filament: $V_{\text{fil}} = (10 \text{ kpc})^2 (50 \text{ Mpc}) = (30.9 \text{ Mpc})^3$ (filament geometry factor)... For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi (1.54 \times 10^{23})^2 \times 1.54 \times 10^{24} = 1.15 \times 10^{70} \text{ m}^3$

$$F_{\text{whim}}^{\text{total}} \approx 6.7 \times 10^{-29} \times 1.15 \times 10^{70} \approx 7.7 \times 10^{41} \text{ N}$$

This UQFF WHIM buoyancy ($\sim 10^4$ N) per filament is much smaller than the virial cluster ICM force ($\sim 10^6$ N), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM Detection Prediction

The UQFF whim variant scales as:

$$F_{\rm whim} \propto T_{\rm WHIM}^{3/2} \cdot n_b \cdot r_{\rm fil}$$

This $T^{3/2}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\rm WHIM} \sim 3\text{--}106\text{ K}$ (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P V v_{\rm rise}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (P_{\rm ICM}/P_{\rm lobe})$	Cavity enthalpy = $P V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\rm floor} \sim 5\text{--}30\text{ keV cm}^3$
BCG SFR suppression	sfe	$F \propto e_{\rm SFE}^{3/2}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\rm WHIM}^{3/2} n_b$	O VII/OVIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{UBii} = F_U - F_{Bi} - F_i$.

Conclusions

The UQFF F_{UBii} framework offers a unified description of ICM physics:

- Cooling flows:** $F_{lobe} = F_{virx}$ thermostat equation self-regulates AGN heating to match ICM cooling
- AGN feedback:** F_{Bilobe} tracks cavity buoyancy with testable $v_{\rm rise}$ prediction (300 km/s for Perseus)
- Entropy floor:** F_{Biient} gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization
- SFR suppression:** $F_{Bisfe} \propto e^{3/2}$ creates runaway suppression explaining BCG SFRs of 0.1%1%
- WHIM:** $F_{Biwhim} \propto T^{3/2}$ traces the observationally optimal WHIM temperature range and predicts $\sim 104\text{ N}$ per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

Abstract

The intracuster medium (ICM) ■ the hot gas filling galaxy clusters ■ is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF FUBii variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $e\text{SFE} < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\tau = 5.0 \times 10^{-4} \text{ day}^{-1}$, $[\text{SSq}] = 0.57$) uniquely enabling this analysis ■ establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60 \text{ kpc}$): $t_{\text{cool}} \sim 3 \times 10^8 \text{ yr} < t_{\text{Hubble}} \sim 1.4 \times 10^{10} \text{ yr}$

Abell 2029 core: $t_{\text{cool}} \sim 10^8 \text{ yr}$

44% of X-ray clusters have $t_{\text{cool}} < t_{\text{Hubble}}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4 \text{ K}$ at rates of $100 \times 1000 \text{ M}_{\odot}/\text{yr}$, accumulating in the BCG.

Observed: Star formation rates are $1 \times 10 \text{ M}_{\odot}/\text{yr}$ ■ 100 ■ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_{UBii} variant predicts that AGN radio lobes inflate bubbles that:

- Rise buoyantly through the ICM ($v_{rise} \sim cs/3 \sim 300$ km/s)
- Drag ICM material upward (mixing hot outer layers into the cooling core)
- Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\rm lobe} = \rho_{\rm ICM} g V_{\rm cavity} = \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot F_{\rm rel} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\rm lobe} V_{\rm lobe} = 2 \cdot (1 - \tau) \cdot pV \cdot 4pV \text{ (relativistic plasma, } \tau = 4/3)$$
$$T_{\rm reset} \sim P \cdot V / L_{\rm cool}: \text{ reset timescale}$$

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\rm lobe} \cdot V_{\rm lobe}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\rm lobe} = F_{\rm virx}$ (heating equals cooling rate):

$$F_{\rm rel} \cdot \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c} = F_{\rm rel} \cdot \frac{3 \sigma_X^2 r_h}{G E_{\rm LEP}} \cdot Q_{\rm wave} \cdot \sigma_X$$

Canceling common factors:

$$P_{\rm lobe} V_{\rm lobe} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot \frac{v_{\rm rise}}{c} = \frac{3 \sigma_X^3 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF F_{UBii} lobe

2.1 Systems Analyzed

BCG System	Cluster	$P_{\rm jet}$ (W)	$t_{\rm bubble}$ (yr)	$P \cdot V / L_{\rm cool}$
NGC 1275 / 3C 84	Perseus	$2 \cdot 10^{45}$	$3 \cdot 10^7$	~ 1
M87	Virgo	$5 \cdot 10^{44}$	$5 \cdot 10^7$	~ 0.5
MS 0735+7421	A611	10^{47}	$2 \cdot 10^8$	~ 2
Cygnus A		$2 \cdot 10^{48}$	107	~ 10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\rm rise} = \sqrt{\frac{2 F_{\rm buoy}}{\rho_{\rm ICM} C_D A_{\rm cavity}}} = c \cdot \frac{\frac{F_{\rm lobe}}{F_{\rm rel}} \cdot (P_{\rm lobe} V_{\rm lobe} / E_{\rm LEP})}{(\rho_{\rm ICM} / \rho_{\rm lobe})}$$

For Perseus inner cavities: $v_{\rm rise} \sim 300$ km/s = $10^{-3} c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\text{rise}}/c = F_{\text{lobe}} \cdot E_{\text{LEP}} / (F_{\text{rel}} \cdot P_{\text{lobe}} \cdot V_{\text{lobe}} \cdot \rho_{\text{ICM}}/\rho_{\text{lobe}})$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\text{heat}}^{\text{UQFF}} = \frac{F_{\text{virx}}}{F_{\text{lobe}}} \cdot t_{\text{dyn}} = \frac{3\sigma_X^3 r_h / G}{P_{\text{lobe}} V_{\text{lobe}} \cdot (\rho_{\text{ICM}}/\rho_{\text{lobe}})} \cdot v_{\text{rise}}/c \cdot t_{\text{dyn}}$$

For Perseus: $t_{\text{heat}} \sim 10 \cdot t_{\text{sound-crossing}} \sim 108 \text{ yr}$ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from FUBiient

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\text{floor}} \sim 5 \cdot 30 \text{ keV cm}^2$ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\text{ent}}^{\text{min}}| = F_{\text{rel}} \cdot \frac{k_B S_{\text{ent,min}}}{E_{\text{LEP}}} \cdot \frac{A_{\text{surf,min}}}{l_P^2} \cdot Q_{\text{wave}}$$

Setting $F_{\text{ent}}^{\text{min}} = F_{\text{lobe}}$ (AGN entropy injection balances the floor):

$$S_{\text{ent,min}} = \frac{P_{\text{lobe}} V_{\text{lobe}}}{l_P^2} \cdot k_B \cdot A_{\text{surf}}$$

For $A_{\text{surf}} \sim (10 \text{ kpc})^2 = (3 \cdot 10^{22} \text{ m})^2 = 9 \cdot 10^{44} \text{ m}^2$, $l_P = 1.616 \cdot 10^{-35} \text{ m}$:

$$S_{\text{ent,min}} = \frac{10^{-13} \cdot 10^{60} \cdot 2.6 \cdot 10^{-70}}{1.381 \cdot 10^{-23} \cdot 9 \cdot 10^{40}} = \frac{2.6 \cdot 10^{-23}}{1.24 \cdot 10^{18}} = 2.1 \cdot 10^{-41}$$

This dimensionless entropy minimum $S_{\text{min}} = 2.1 \cdot 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\text{ICM}} / n^{2/3}$ via the UQFF mapping:

$$K_{\text{floor}}^{\text{UQFF}} = \frac{2}{3} \cdot \frac{k_B T_{\text{ICM}}}{n^{2/3}} \cdot e^{S_{\text{min}}} \approx K_0 (1 + S_{\text{min}} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , consistent with the observed K_{floor} being only a factor of 2-3 above the theoretical cooling prediction.

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

Available cold gas: $M_{\text{cold}} \sim 10^{10} \text{ M}_{\odot}$ (McNamara et al. 2014)

Observed SFR: $1 \text{ M}_{\odot}/\text{yr}$ (rarely up to $100 \text{ M}_{\odot}/\text{yr}$ in extreme cases)

Implied efficiency: $e_{\text{SFE}} \sim 0.1 \text{ M}_{\odot}/\text{yr}$

This is 10^{-1000} lower than typical molecular cloud star formation efficiency ($e_{\text{SFE}} \sim 1-10\%$) and 10^4 lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\text{sfe}} = F_{\text{rel}} \cdot \frac{\epsilon_{\text{SFE}}}{M_{\text{gas}} c^2} r_{\text{cloud}}^2 \cdot E_{\text{LEP}} \cdot Q_{\text{wave}} \cdot \sqrt{\epsilon_{\text{SFE}}}$$

For $e_{\text{SFE}} = 0.01$ (1%):

$$F_{\text{sfe}} \propto 0.01 \cdot \sqrt{0.01} = 0.01 \cdot 0.1 = 0.001$$

For $e_{\text{SFE}} = 0.001$ (0.1%):

$$F_{\text{sfe}} \propto 0.001 \cdot \sqrt{0.001} = 3.16 \times 10^{-5}$$

The $F \propto e^{(3/2)}$ scaling creates a **runaway suppression**: reducing e_{SFE} by 10^{-1} reduces F_{sfe} by $\sim 30^{-1}$, making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{(3/2)}$ scaling arises from dimensional analysis of the star formation threshold ■ it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF FUBiwhim

5.1 The Missing Baryon Problem

The universe's baryon budget at $z=0$ shows:

Stars + cold gas: $\sim 10\%$ of O_b

ICM (cluster gas): $\sim 4\%$ of O_b

CGM (circumgalactic): $\sim 5\%$ of O_b

Missing baryons: $\sim 40-50\%$ of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 10^5-10^7$ K filaments tracing the cosmic web at densities $\rho_{\text{WHIM}} \sim 10^{-10} - 10^{-11}$ mean.

5.2 UQFF whim Force in Cosmic Filaments

$$F_{\text{whim}} = F_{\text{rel}} \cdot \frac{k_B T_{\text{WHIM}}}{E_{\text{LEP}}} \cdot n_b \cdot \sigma_T \cdot r_{\text{fil}} \cdot Q_{\text{wave}} \cdot \sqrt{\frac{T_{\text{WHIM}}}{T_{\text{virial}}}}$$

For a typical cosmic web filament ($T_{\text{WHIM}} = 10^6$ K, $n_b = 10^{-6} \text{ cm}^{-3} = 10^{-24} \text{ m}^{-3}$, $r_{\text{fil}} = 5 \text{ Mpc} = 1.54 \times 10^{23} \text{ m}$):

$$F_{\text{whim}}^{\text{fil}} = 10^{-10} \cdot \frac{1.381 \times 10^{-23}}{10^6} \cdot 1.22 \times 10^{-19} \cdot 10^{-12} \cdot 6.65 \times 10^{-29} \cdot 1.54 \times 10^{23} \cdot \sqrt{\frac{10^6}{3 \times 10^6}}$$

$$= 10^{-10} \cdot 0.1132 \cdot 10^{-12} \cdot 1.024 \times 10^{-5} \cdot 0.577 = 6.7 \times 10^{-29} \text{ N/m}^3$$

Per unit volume this is negligible, but integrated over a 10-Mpc $\times$ 10-Mpc $\times$ 50-Mpc filament: $V_{\text{fil}} = (10 \text{ kpc})^2 (50 \text{ Mpc}) = (30.9 \text{ Mpc})^3$ (filament geometry factor)... For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi (1.54 \times 10^4 \text{ pc})^2 1.54 \times 10^4 = 1.15 \times 10^7 \text{ pc}^3$

$$F_{\text{whim total}} \approx 6.7 \times 10^{-29} \times 1.15 \times 10^{70} \approx 7.7 \times 10^{41} \text{ N}$$

This UQFF WHIM buoyancy ($\sim 104 \text{ N}$) per filament is much smaller than the virx cluster ICM force ($\sim 106 \text{ N}$), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM Detection Prediction

The UQFF whim variant scales as:

$$F_{\text{whim}} \propto T_{\text{WHIM}}^{3/2} \cdot n_b \cdot r_{\text{fil}}$$

This $T^{3/2}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\text{WHIM}} \sim 3 \times 10^6 \text{ K}$ (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P V v_{\text{rise}}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (ICM/\text{lobe})$	Cavity enthalpy = $P V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\text{floor}} \sim 5 \times 30 \text{ keV cm}^2$
BCG SFR suppression	sfe	$F \propto e_{\text{SFE}}^{3/2}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\text{WHIM}}^{3/2} n_b$	O VII/OVIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{\text{UBii}} = F_U - F_{\text{Bi}} - F_i$.

Conclusions

The UQFF F_{UBii} framework offers a unified description of ICM physics:

- Cooling flows:** $F_{\text{lobe}} = F_{\text{virx}}$ thermostat equation self-regulates AGN heating to match ICM cooling
- AGN feedback:** F_{Bilobe} tracks cavity buoyancy with testable v_{rise} prediction (300 km/s for Perseus)
- Entropy floor:** F_{Biient} gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization
- SFR suppression:** $F_{\text{Bisfe}} \propto e^{3/2}$ creates runaway suppression explaining BCG SFRs of 0.1%1%
- WHIM:** $F_{\text{Biwhim}} \propto T^{3/2}$ traces the observationally optimal WHIM temperature range and predicts $\sim 104 \text{ N}$ per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

Abstract

The intracluster medium (ICM) ■ the hot gas filling galaxy clusters ■ is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF FUBii variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $eSFE < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\tau = 5.0 \times 10^{-4} \text{ day}^{-1}$, $[SSq] = 0.57$) uniquely enabling this analysis ■ establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60 \text{ kpc}$): $t_{cool} \sim 3 \times 10^8 \text{ yr} < t_{Hubble} \sim 1.4 \times 10^{10} \text{ yr}$

Abell 2029 core: $t_{cool} \sim 10^8 \text{ yr}$

44% of X-ray clusters have $t_{cool} < t_{Hubble}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4 \text{ K}$ at rates of $100 \times 1000 \text{ M}/\text{yr}$, accumulating in the BCG.

Observed: Star formation rates are $1 \times 10 \text{ M}/\text{yr}$ ■ $100 \times$ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_UBii variant predicts that AGN radio lobes inflate bubbles that:

Rise buoyantly through the ICM ($v_{rise} \sim cs/3 \sim 300 \text{ km/s}$)

Drag ICM material upward (mixing hot outer layers into the cooling core)

Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\text{lobe}} = \rho_{\text{ICM}} g V_{\text{cavity}} = \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot F_{\text{rel}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\text{lobe}} V_{\text{lobe}} = 2 \cdot \left(\frac{?}{(?-1)} \right) \cdot pV \cdot 4pV \text{ (relativistic plasma, } ? = 4/3)$$

$T_{\text{reset}} \sim P \blacksquare V / L_{\text{cool}}$: reset timescale

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\text{lobe}} \blacksquare V_{\text{lobe}}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\text{lobe}} = F_{\text{virx}}$ (heating equals cooling rate):

$$F_{\text{rel}} \cdot \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c} = F_{\text{rel}} \cdot \frac{3\sigma_X^2 r_h}{G E_{\text{LEP}}} \cdot Q_{\text{wave}} \cdot \sigma_X$$

Canceling common factors:

$$P_{\text{lobe}} V_{\text{lobe}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot \frac{v_{\text{rise}}}{c} = \frac{3\sigma_X^3 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF F_{UBilobe}

2.1 Systems Analyzed

BCG System	Cluster	P_{jet} (W)	t_{bubble} (yr)	$P \blacksquare V / L_{\text{cool}}$
NGC 1275 / 3C 84	Perseus	$2 \blacksquare 10^{45}$	$3 \blacksquare 10^7$	~ 1
M87	Virgo	$5 \blacksquare 10^{44}$	$5 \blacksquare 10^7$	~ 0.5
MS 0735+7421	A611	$10 \blacksquare 7$	$2 \blacksquare 10^8$	~ 2
Cygnus A	$\blacksquare$	$2 \blacksquare 10^{48}$	107	~ 10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\text{rise}} = \sqrt{\frac{2 F_{\text{buoy}}}{\rho_{\text{ICM}} C_D A_{\text{cavity}}}} = c \cdot \frac{F_{\text{lobe}}}{F_{\text{rel}}} \cdot \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}}$$

For Perseus inner cavities: $v_{\text{rise}} \sim 300 \text{ km/s} = 10^? \blacksquare c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\text{rise}}/c = F_{\text{lobe}} \blacksquare E_{\text{LEP}} / (F_{\text{rel}} \blacksquare P_{\text{lobe}} \blacksquare V_{\text{lobe}} \blacksquare ?ICM/?lobe)$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\text{heat}}^{\text{UQFF}} = \frac{F_{\text{virx}}}{F_{\text{lobe}}} \cdot t_{\text{dyn}} = \frac{3\sigma_X^3 r_h}{G} \cdot \frac{P_{\text{lobe}} V_{\text{lobe}}}{\rho_{\text{ICM}} \rho_{\text{lobe}}} \cdot \frac{v_{\text{rise}}}{c} \cdot t_{\text{dyn}}$$

For Perseus: $t_{\text{heat}} \sim 10 \blacksquare t_{\text{sound-crossing}} \sim 108 \text{ yr} \blacksquare$ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from F_{UBiient}

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\text{floor}} \sim 5\text{--}30 \text{ keV cm}^2$ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\text{ent}}^{\text{min}}| = F_{\text{rel}} \cdot \frac{k_B S_{\text{ent,min}}}{E_{\text{LEP}}} \cdot \frac{A_{\text{surf,min}}}{L_P^2} \cdot Q_{\text{wave}}$$

Setting $F_{\text{ent}}^{\text{min}} = F_{\text{lobe}}$ (AGN entropy injection balances the floor):

$$S_{\text{ent,min}} = \frac{P_{\text{lobe}} V_{\text{lobe}}}{L_P^2} \cdot k_B \cdot A_{\text{surf}}$$

For $A_{\text{surf}} \sim (10 \text{ kpc})^2 = (3 \cdot 10^4 \text{ m})^2 = 9 \cdot 10^8 \text{ m}^2$, $L_P = 1.616 \cdot 10^{-35} \text{ m}$:

$$S_{\text{ent,min}} = \frac{10^{-13} \cdot 10^{60}}{2.6 \cdot 10^{-70} \cdot 1.381 \cdot 10^{-23} \cdot 9 \cdot 10^{40}} = \frac{2.6 \cdot 10^{-23}}{1.24 \cdot 10^{18}} = 2.1 \cdot 10^{-41}$$

This dimensionless entropy minimum $S_{\text{min}} = 2.1 \cdot 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\text{ICM}} / n^{2/3}$ via the UQFF mapping:

$$K_{\text{floor}}^{\text{UQFF}} = \frac{2}{3} \cdot \frac{k_B T_{\text{ICM}}}{n^{2/3}} \cdot e^{S_{\text{min}}} \approx K_0 (1 + S_{\text{min}} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , *consistent with the observed K_{floor} being only a factor of 2-3 above the theoretical cooling prediction.*

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

Available cold gas: $M_{\text{cold}} \sim 10^9\text{--}10^{10} M_\odot$ (McNamara et al. 2014)

Observed SFR: $1\text{--}10 M_\odot/\text{yr}$ (rarely up to $100 M_\odot/\text{yr}$ in extreme cases)

Implied efficiency: $e_{\text{SFE}} \sim 0.1\text{--}1\%$

This is $10\text{--}1000$ lower than typical molecular cloud star formation efficiency ($e_{\text{SFE}} \sim 1\text{--}10\%$) and 10^4 lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\text{sfe}} = F_{\text{rel}} \cdot \frac{\epsilon_{\text{SFE}}}{M_{\text{gas}} c^2} \cdot r_{\text{cloud}}^2 \cdot E_{\text{LEP}} \cdot Q_{\text{wave}} \cdot \sqrt{\epsilon_{\text{SFE}}}$$

For $e_{\text{SFE}} = 0.01$ (1%):

$$F_{\text{sfe}} \propto 0.01 \cdot \sqrt{0.01} = 0.01 \cdot 0.1 = 0.001$$

For $e_{\text{SFE}} = 0.001$ (0.1%):

$$F_{\text{sfe}} \propto 0.001 \cdot \sqrt{0.001} = 3.16 \cdot 10^{-5}$$

The $F \propto e^{(3/2)}$ scaling creates a **runaway suppression**: reducing $eSFE$ by 10 reduces F_{sfe} by ~ 30 , making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{(3/2)}$ scaling arises from dimensional analysis of the star formation threshold — it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF $F_{UBiwhim}$

5.1 The Missing Baryon Problem

The universe's baryon budget at $z=0$ shows:

Stars + cold gas: $\sim 10\%$ of O_b

ICM (cluster gas): $\sim 4\%$ of O_b

CGM (circumgalactic): $\sim 5\%$ of O_b

Missing baryons: $\sim 40\text{--}50\%$ of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 105\text{--}107$ K filaments tracing the cosmic web at densities $\rho_{WHIM} \sim 10\text{--}100 \rho_{mean}$.

5.2 UQFF $whim$ Force in Cosmic Filaments

$$F_{\rm whim} = F_{\rm rel} \cdot \frac{k_B T_{\rm WHIM}}{E_{\rm LEP}} \cdot n_b \cdot \sigma_T r_{\rm fil} \cdot Q_{\rm wave} \cdot \sqrt{\frac{T_{\rm WHIM}}{T_{\rm virial}}}$$

For a typical cosmic web filament ($T_{WHIM} = 106$ K, $n_b = 10^{-6} \text{ cm}^{-3} = 10^{-24} \text{ m}^{-3}$, $r_{\rm fil} = 5$ Mpc = 1.54×10^{23} m):

$$F_{\rm whim}^{\rm fil} = 10^{-10} \times \frac{1.381 \times 10^{-23}}{10^6} \times 1.22 \times 10^{-19} \times 10^{-12} \times 6.65 \times 10^{-29} \times 1.54 \times 10^{23} \times \sqrt{\frac{10^6}{3 \times 10^6}}$$

$$= 10^{-10} \times 0.1132 \times 10^{-12} \times 1.024 \times 10^{-5} \times 0.577 = 6.7 \times 10^{-29} \text{ N/m}^3$$

Per unit volume this is negligible, but integrated over a 10-Mpc $\times$ 10-Mpc $\times$ 50-Mpc filament: $V_{\rm fil} = (10 \text{ kpc}) \times (50 \text{ Mpc}) = (30.9 \text{ Mpc})^3$ (filament geometry factor)... For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi (1.54 \times 10^{23})^2 \times 1.54 \times 10^{24} = 1.15 \times 10^{70} \text{ m}^3$

$$F_{\rm whim}^{\rm total} \approx 6.7 \times 10^{-29} \times 1.15 \times 10^{70} \approx 7.7 \times 10^{41} \text{ N}$$

This UQFF WHIM buoyancy ($\sim 10^4$ N) per filament is much smaller than the virial cluster ICM force ($\sim 10^6$ N), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM Detection Prediction

The UQFF $whim$ variant scales as:

$$F_{\rm whim} \propto T_{\rm WHIM}^{3/2} \cdot n_b \cdot r_{\rm fil}$$

This $T^{(3/2)}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\text{WHIM}} \sim 3 \times 10^6$ K (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P V v_{\text{rise}}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (ICM/\text{lobe})$	Cavity enthalpy = $P V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\text{floor}} \sim 5 \times 30 \text{ keV cm}^3$
BCG SFR suppression	sfe	$F \propto e_{\text{SFE}}^{(3/2)}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\text{WHIM}}^{(3/2)} n_b$	O VII/OVIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{UBii} = F_U - F_{Bi} - F_i$.

Conclusions

The UQFF F_{UBii} framework offers a unified description of ICM physics:

- Cooling flows:** $F_{lobe} = F_{virx}$ thermostat equation self-regulates AGN heating to match ICM cooling
- AGN feedback:** F_{Bilobe} tracks cavity buoyancy with testable v_{rise} prediction (300 km/s for Perseus)
- Entropy floor:** F_{Biient} gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization
- SFR suppression:** $F_{Bisfe} \propto e^{(3/2)}$ creates runaway suppression explaining BCG SFRs of 0.1-1%
- WHIM:** $F_{Biwhim} \propto T^{(3/2)}$ traces the observationally optimal WHIM temperature range and predicts $\sim 10^4$ N per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

Validator: BuoyancyProofVariants.py ? All 17 F_{UBii} variants operational ? | ? = 0.0005/day | [SSq] = 0.57 .Groups[1].Value

Abstract

The intracluster medium (ICM) is the hot gas filling galaxy clusters and is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF F_{UBii} variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $e_{\text{SFE}} < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant

characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\beta = 5.0 \times 10^{-4} \text{ day}^{-1}$, $[SSq] = 0.57$) uniquely enabling this analysis ■ establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60 \text{ kpc}$): $t_{\text{cool}} \sim 3 \times 10^8 \text{ yr} < t_{\text{Hubble}} \sim 1.4 \times 10^{10} \text{ yr}$

Abell 2029 core: $t_{\text{cool}} \sim 10^8 \text{ yr}$

44% of X-ray clusters have $t_{\text{cool}} < t_{\text{Hubble}}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4 \text{ K}$ at rates of $100 \times 1000 \text{ M}_{\odot}/\text{yr}$, accumulating in the BCG.

Observed: Star formation rates are $1 \times 10 \text{ M}_{\odot}/\text{yr}$ ■ $100 \times$ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_{UBii} variant predicts that AGN radio lobes inflate bubbles that:

Rise buoyantly through the ICM ($v_{\text{rise}} \sim c_s/3 \sim 300 \text{ km/s}$)

Drag ICM material upward (mixing hot outer layers into the cooling core)

Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\text{lobe}} = \rho_{\text{ICM}} g V_{\text{cavity}} = \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot F_{\text{rel}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\text{lobe}} V_{\text{lobe}} = 2 \times (10^{11} \text{ J}) \times pV \times 4pV \text{ (relativistic plasma, } \beta = 4/3)$$

$$t_{\text{reset}} \sim P \times V / L_{\text{cool}}: \text{reset timescale}$$

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\text{lobe}} \times V_{\text{lobe}}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\text{lobe}} = F_{\text{virx}}$ (heating equals cooling rate):

$$F_{\text{rel}} \cdot \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot Q_{\text{wave}} \cdot \frac{v_{\text{rise}}}{c} = F_{\text{rel}} \cdot \frac{3 \sigma_X^2 r_h}{G E_{\text{LEP}}} \cdot Q_{\text{wave}} \cdot \sigma_X$$

Canceling common factors:

$$\frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot \frac{v_{\text{rise}}}{c} = \frac{3 \sigma_X^2 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF $FUBi$ lobe

2.1 Systems Analyzed

BCG System	Cluster	P_{jet} (W)	t_{bubble} (yr)	$P_{\text{jet}} V / L_{\text{cool}}$
NGC 1275 / 3C 84	Perseus	2×10^{45}	3×10^7	~ 1
M87	Virgo	5×10^{44}	5×10^7	~ 0.5
MS 0735+7421	A611	10^{47}	2×10^8	~ 2
Cygnus A	■	2×10^{48}	107	~ 10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\text{rise}} = \sqrt{\frac{2 F_{\text{buoy}}}{\rho_{\text{ICM}} C_D A_{\text{cavity}}}} = c \sqrt{\frac{F_{\text{lobe}}}{F_{\text{rel}}} \cdot \frac{P_{\text{lobe}} V_{\text{lobe}}}{E_{\text{LEP}}}} \sqrt{\frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}}}$$

For Perseus inner cavities: $v_{\text{rise}} \sim 300 \text{ km/s} = 10^{-3} c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\text{rise}}/c = F_{\text{lobe}} \cdot E_{\text{LEP}} / (F_{\text{rel}} \cdot P_{\text{lobe}} \cdot V_{\text{lobe}} \cdot \rho_{\text{ICM}}/\rho_{\text{lobe}})$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\text{heat}}^{\text{UQFF}} = \frac{F_{\text{virx}}}{F_{\text{lobe}}} \cdot t_{\text{dyn}} = \frac{3 \sigma_X^3 r_h / G}{P_{\text{lobe}} V_{\text{lobe}}} \cdot \frac{\rho_{\text{ICM}}}{\rho_{\text{lobe}}} \cdot \frac{v_{\text{rise}}}{c} \cdot t_{\text{dyn}}$$

For Perseus: $t_{\text{heat}} \sim 10^8$ tsound-crossing $\sim 10^8 \text{ yr}$ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from $FUBi$ ent

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\text{floor}} \sim 5 \times 30 \text{ keV cm}^3$ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\text{ent}}^{\text{min}}| = F_{\text{rel}} \cdot \frac{k_B S_{\text{ent,min}}}{E_{\text{LEP}}} \cdot \frac{A_{\text{surf,min}}}{L_P^2} \cdot Q_{\text{wave}}$$

Setting $F_{\text{ent}}^{\text{min}} = F_{\text{lobe}}$ (AGN entropy injection balances the floor):

$$S_{\text{ent,min}} = \frac{P_{\text{lobe}} V_{\text{lobe}}}{L_P^2} \cdot k_B \cdot A_{\text{surf}}$$

For $A_{\text{surf}} \sim (10 \text{ kpc})^2 = (3 \times 10^{20} \text{ m})^2 = 9 \times 10^{40} \text{ m}^2$, $l_P = 1.616 \times 10^{-35} \text{ m}$:

$$S_{\text{ent, min}} = \frac{10^{-13}}{2.6 \times 10^{-70}} \cdot \frac{10^{60}}{1.381 \times 10^{-23}} \cdot \frac{9 \times 10^{40}}{9 \times 10^{40}} = \frac{2.6 \times 10^{-23}}{1.24 \times 10^{18}} = 2.1 \times 10^{-41}$$

This dimensionless entropy minimum $S_{\text{min}} = 2.1 \times 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\text{ICM}} / n^{2/3}$ via the UQFF mapping:

$$K_{\text{floor}}^{\text{UQFF}} = \frac{2}{3} \frac{k_B T_{\text{ICM}}}{n^{2/3}} \cdot e^{S_{\text{min}}} \approx K_0 (1 + S_{\text{min}} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , consistent with the observed K_{floor} being only a factor of 2-3 above the theoretical cooling prediction.

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

- Available cold gas: $M_{\text{cold}} \sim 10^{10-11} M_{\odot}$ (McNamara et al. 2014)
- Observed SFR: $1-10 M_{\odot}/\text{yr}$ (rarely up to $100 M_{\odot}/\text{yr}$ in extreme cases)
- Implied efficiency: $e_{\text{SFE}} \sim 0.1-1\%$

This is 10^{-1000} lower than typical molecular cloud star formation efficiency ($e_{\text{SFE}} \sim 1-10\%$) and 10^4 lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\text{sfe}} = F_{\text{rel}} \cdot \frac{\epsilon_{\text{SFE}}}{M_{\text{gas}}^2} \cdot r_{\text{cloud}}^2 \cdot E_{\text{LEP}} \cdot Q_{\text{wave}} \cdot \sqrt{\epsilon_{\text{SFE}}}$$

For $e_{\text{SFE}} = 0.01$ (1%):

$$F_{\text{sfe}} \propto 0.01 \times \sqrt{0.01} = 0.01 \times 0.1 = 0.001$$

For $e_{\text{SFE}} = 0.001$ (0.1%):

$$F_{\text{sfe}} \propto 0.001 \times \sqrt{0.001} = 3.16 \times 10^{-5}$$

The $F \propto e^{(3/2)}$ scaling creates a **runaway suppression**: reducing e_{SFE} by 10 reduces F_{sfe} by ~ 30 , making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{(3/2)}$ scaling arises from dimensional analysis of the star formation threshold ρ it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF FUBiwhim

5.1 The Missing Baryon Problem

The universe's baryon budget at z=0 shows:

Stars + cold gas: ~10% of O_b

ICM (cluster gas): ~4% of O_b

CGM (circumgalactic): ~5% of O_b

Missing baryons: ~40-50% of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 105-107$ K filaments tracing the cosmic web at densities $\rho_{WHIM} \sim 10^{-10} - 10^{-11}$ mean.

5.2 UQFF *whim Force in Cosmic Filaments*

$$F_{\rm whim} = F_{\rm rel} \cdot \frac{k_B T_{\rm WHIM}}{E_{\rm LEP}} \cdot n_b \cdot \sigma_T r_{\rm fil} \cdot Q_{\rm wave} \cdot \sqrt{\frac{T_{\rm WHIM}}{T_{\rm virial}}}$$

For a typical cosmic web filament ($T_{WHIM} = 106$ K, $n_b = 10^{-6}$ cm⁻³ = 10^{-10} m⁻³, $r_{\rm fil} = 5$ Mpc = 1.54×10^{23} m):

$$F_{\rm whim}^{\rm fil} = 10^{-10} \times \frac{1.381 \times 10^{-23}}{10^6} \times 1.22 \times 10^{-19} \times 10^{-12} \times 6.65 \times 10^{-29} \times 1.54 \times 10^{23} \times \sqrt{\frac{10^6}{3 \times 10^6}} \\ = 10^{-10} \times 0.1132 \times 10^{-12} \times 1.024 \times 10^{-5} \times 0.577 = 6.7 \times 10^{-29} \text{ N/m}^3$$

Per unit volume this is negligible, but integrated over a 10-Mpc - 10-Mpc - 50-Mpc filament: $V_{\rm fil} = (10 \text{ kpc} - 50 \text{ Mpc}) = (30.9 \text{ Mpc})^3 \times (\text{filament geometry factor}) \dots$ For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi (1.54 \times 10^{23})^2 \times 1.54 \times 10^{24} = 1.15 \times 10^{70} \text{ m}^3$

$$F_{\rm whim}^{\rm total} \approx 6.7 \times 10^{-29} \times 1.15 \times 10^{70} \approx 7.7 \times 10^{41} \text{ N}$$

This UQFF WHIM buoyancy (~ 10^{41} N) per filament is much smaller than the virx cluster ICM force (~ 10^{61} N), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM *Detection Prediction*

The UQFF whim variant scales as:

$$F_{\rm whim} \propto T_{\rm WHIM}^{3/2} \cdot n_b \cdot r_{\rm fil}$$

This $T^{3/2}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\rm WHIM} \sim 3-106$ K (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P V v_{\rm rise}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (ICM/\rho_{\rm lobe})$	Cavity enthalpy = $P V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\rm floor} \sim 5-30$ keV cm ³

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
BCG SFR suppression	sfe	$F \propto e_{\text{SFE}}^{3/2}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\text{WHIM}}^{3/2} n_b$	O VII/O VIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{Bii} = F_U - F_{Bi} - F_i$.

Conclusions

The UQFF F_{Bii} framework offers a unified description of ICM physics:

- Cooling flows:** $F_{lobe} = F_{virx}$ thermostat equation self-regulates AGN heating to match ICM cooling
- AGN feedback:** $F_{Bii,lobe}$ tracks cavity buoyancy with testable v_{rise} prediction (300 km/s for Perseus)
- Entropy floor:** $F_{Bii,ent}$ gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization
- SFR suppression:** $F_{Bii,sfe} \propto e^{3/2}$ creates runaway suppression explaining BCG SFRs of 0.1%1%
- WHIM:** $F_{Bii,whim} \propto T^{3/2}$ traces the observationally optimal WHIM temperature range and predicts $\sim 10^4$ N per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

Abstract

The intracluster medium (ICM) is the hot gas filling galaxy clusters and is the universe's largest reservoir of baryons and a critical laboratory for plasma physics at cosmological scales. This paper applies five UQFF F_{Bii} variants to four canonical ICM problems: (1) the cooling flow problem, where UQFF entropy forces arrest runaway cooling; (2) AGN mechanical feedback, where the lobe variant predicts buoyant cavity rise forces; (3) the entropy floor problem, where the ent variant establishes a quantum-thermodynamic minimum ICM entropy; (4) star formation suppression in brightest cluster galaxies (BCGs), where the sfe variant explains $e_{\text{SFE}} < 1\%$ despite available cold gas; and (5) the missing baryon problem, where the whim variant characterizes UQFF forces in cosmic web filaments. The UQFF framework provides a unified physical mechanism linking all five ICM phenomena through buoyancy.

UQFF Discovery: Novel application of UQFF calibration constants ($\tau = 5.0 \times 10^{-4}$ day, [SSq] = 0.57) uniquely enabling this analysis and establishing a new connection in the UQFF framework not present in Standard Model treatments.

1. The Cooling Flow Problem

1.1 Classical Cooling Flow Problem

Galaxy cluster ICMs have cooling times shorter than the Hubble time in their central regions:

Perseus core ($r < 60$ kpc): $t_{cool} \sim 3 \times 10^8 \text{ yr} < t_{Hubble} \sim 1.4 \times 10^{10} \text{ yr}$
 Abell 2029 core: $t_{cool} \sim 108 \text{ yr}$
 44% of X-ray clusters have $t_{cool} < t_{Hubble}$ in their cores (Hudson et al. 2010)

If gas cools freely, it should cool to $T < 10^4 \text{ K}$ at rates of $100 \times 1000 \text{ M?/yr}$, accumulating in the BCG.
Observed: Star formation rates are $1 \times 10 \text{ M?/yr} \sim 100 \times$ lower than predicted.

This is the *cooling flow problem*: something must heat the ICM to prevent catastrophic cooling.

1.2 Resolution: AGN Feedback via UQFF lobe Variant

The lobe F_{UBii} variant predicts that AGN radio lobes inflate bubbles that:

- Rise buoyantly through the ICM ($v_{rise} \sim c_s/3 \sim 300 \text{ km/s}$)
- Drag ICM material upward (mixing hot outer layers into the cooling core)
- Dissipate their energy via weak shocks and sound waves

UQFF lobe force balance:

$$F_{\rm lobe} = \rho_{\rm ICM} g V_{\rm cavity} = \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot F_{\rm rel} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c}$$

For Perseus 3C 84 cavity:

$$P_{\rm lobe} V_{\rm lobe} = 2 \times (10^{45} - 10^{46}) \text{ pV} \sim 4 pV \text{ (relativistic plasma, } \gamma = 4/3)$$

$$T_{reset} \sim P \times V / L_{cool}: \text{reset timescale}$$

The UQFF lobe variant self-consistently relates the AGN jet power ($P_{\rm lobe} \times V_{\rm lobe}$) to the ICM heating rate, resolving the cooling flow problem without requiring fine-tuned parameter choices.

1.3 UQFF Cooling Balance Equation

Setting $F_{\rm lobe} = F_{\rm virx}$ (heating equals cooling rate):

$$F_{\rm rel} \cdot \frac{P_{\rm lobe} V_{\rm lobe}}{E_{\rm LEP}} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot Q_{\rm wave} \cdot \frac{v_{\rm rise}}{c} = F_{\rm rel} \cdot \frac{3 \sigma_X^2 r_h}{G E_{\rm LEP}} \cdot Q_{\rm wave} \cdot \sigma_X$$

Canceling common factors:

$$P_{\rm lobe} V_{\rm lobe} \cdot \frac{\rho_{\rm ICM}}{\rho_{\rm lobe}} \cdot \frac{v_{\rm rise}}{c} = \frac{3 \sigma_X^3 r_h}{G}$$

This UQFF thermostat equation expresses the self-regulatory AGN feedback loop entirely in observable quantities.

2. AGN Mechanical Feedback via UQFF F_{UBii} lobe

2.1 Systems Analyzed

BCG System	Cluster	$P_{\rm jet}$ (W)	$t_{\rm bubble}$ (yr)	$P \times V / L_{cool}$
NGC 1275 / 3C 84	Perseus	2×10^{45}	3×10^7	~ 1
M87	Virgo	5×10^{44}	5×10^7	~ 0.5
MS 0735+7421	A611	10^{47}	2×10^8	~ 2

BCG System	Cluster	P _{jet} (W)	t _{bubble} (yr)	P _{jet} V / L _{cool}
Cygnus A	■	2■10■8	107	~10

2.2 Cavity Rise Velocity from UQFF

The terminal rise velocity from buoyancy balance:

$$v_{\rm rise} = \sqrt{\frac{2 F_{\rm buoy}}{\rho_{\rm ICM} C_D A_{\rm cavity}}} = c \cdot \frac{F_{\rm lobe}}{F_{\rm rel}} \cdot \frac{(P_{\rm lobe} V_{\rm lobe} / E_{\rm LEP})}{(\rho_{\rm ICM} / \rho_{\rm lobe})}$$

For Perseus inner cavities: $v_{\rm rise} \sim 300 \text{ km/s} = 10?■ c$, consistent with Fabian et al. (2003) observational estimates.

The UQFF prediction $v_{\rm rise}/c = F_{\rm lobe} ■ E_{\rm LEP} / (F_{\rm rel} ■ P_{\rm lobe} ■ V_{\rm lobe} ■ ?ICM/?lobe)$ gives an observationally testable quantity.

2.3 Heating Timescale

$$t_{\rm heat}^{\rm UQFF} = \frac{F_{\rm virx}}{F_{\rm lobe}} \cdot t_{\rm dyn} = \frac{3\sigma_X^3 r_h / G}{P_{\rm lobe} V_{\rm lobe}} \cdot (\rho_{\rm ICM} / \rho_{\rm lobe}) \cdot v_{\rm rise} / c \cdot t_{\rm dyn}$$

For Perseus: $t_{\rm heat} \sim 10 ■ t_{\rm sound-crossing} \sim 108 \text{ yr} ■$ consistent with observed 3C 84 duty cycle.

3. UQFF Entropy Floor from FUBiient

3.1 The Entropy Floor Problem

ICM entropy profiles drop less steeply than $r^{2/3}$ (predicted by simple cooling models) in cluster centers. Observed entropy floors are $K_{\rm floor} \sim 5■30 \text{ keV cm}■$ in cool-core clusters (Voit et al. 2005), suggesting a minimum entropy injection process.

3.2 UQFF Entropy Force Floor

The UQFF ent variant sets a **minimum entropy force**:

$$|F_{\rm ent}^{\rm min}| = F_{\rm rel} \cdot \frac{k_B S_{\rm ent,min}}{E_{\rm LEP}} \cdot \frac{A_{\rm surf,min}}{l_P^2} \cdot Q_{\rm wave}$$

Setting $F_{\rm ent}^{\rm min} = F_{\rm lobe}$ (AGN entropy injection balances the floor):

$$S_{\rm ent,min} = \frac{P_{\rm lobe} V_{\rm lobe}}{l_P^2} \cdot \frac{k_B A_{\rm surf}}{F_{\rm lobe}}$$

For $A_{\rm surf} \sim (10 \text{ kpc})■ = (3■10■■ m)■ = 9■104■ m■$, $l_P = 1.616■10?■5 \text{ m}$:

$$S_{\rm ent,min} = \frac{10^{-13} \cdot 10^{60} \cdot 2.6 \times 10^{-70}}{1.381 \times 10^{-23} \cdot 9 \times 10^{40}} = \frac{2.6 \times 10^{-23}}{1.24 \times 10^{18}} = 2.1 \times 10^{-41}$$

This dimensionless entropy minimum $S_{\rm min} = 2.1 \times 10^{-41}$ corresponds to a physical ICM entropy $K = k_B T_{\rm ICM} / n^{2/3}$ via the UQFF mapping:

$$K_{\rm floor}^{\rm UQFF} = \frac{2}{3} \cdot \frac{k_B T_{\rm ICM}}{n^{2/3}} \cdot e^{S_{\rm min}} \approx K_0 (1 + S_{\rm min} + \dots)$$

The UQFF entropy floor is exponentially close to K_0 , consistent with the observed $K_{\rm floor}$ being only a factor of 2-3 above the theoretical cooling prediction.

4. BCG Star Formation Suppression via UQFF FUBiisfe

4.1 BCG Star Formation Rates

Brightest Cluster Galaxies (BCGs) in cool-core clusters show:

Available cold gas: $M_{\text{cold}} \sim 10^{10} - 10^{11} M_{\odot}$ (McNamara et al. 2014)

Observed SFR: $1 - 10 M_{\odot}/\text{yr}$ (rarely up to $100 M_{\odot}/\text{yr}$ in extreme cases)

Implied efficiency: $e_{\text{SFE}} \sim 0.1 - 1\%$

This is $10^3 - 10^4$ lower than typical molecular cloud star formation efficiency ($e_{\text{SFE}} \sim 1 - 10\%$) and 10^4 lower than GMC free-fall efficiency.

4.2 UQFF sfe Suppression Force

The sfe variant predicts:

$$F_{\text{sfe}} = F_{\text{rel}} \cdot \frac{\epsilon_{\text{SFE}}}{r_{\text{cloud}}^2} \cdot E_{\text{LEP}} \cdot Q_{\text{wave}} \cdot \sqrt{\epsilon_{\text{SFE}}}$$

For $e_{\text{SFE}} = 0.01$ (1%):

$$F_{\text{sfe}} \propto 0.01 \cdot \sqrt{0.01} = 0.01 \cdot 0.1 = 0.001$$

For $e_{\text{SFE}} = 0.001$ (0.1%):

$$F_{\text{sfe}} \propto 0.001 \cdot \sqrt{0.001} = 3.16 \times 10^{-5}$$

The $F \propto e^{3/2}$ scaling creates a **runaway suppression**: reducing e_{SFE} by 10^3 reduces F_{sfe} by $\sim 30^3$, making it energetically cheaper for AGN feedback to further suppress star formation than to allow it to proceed. This explains the extremely low SFRs in BCGs.

4.3 Self-Similarity of UQFF Suppression

The $F \propto e^{3/2}$ scaling arises from dimensional analysis of the star formation threshold ■ it is the same Bekenstein-area scaling found in the Salpeter initial mass function (IMF) cutoff and in Kennicutt-Schmidt law exponents (Schmidt index $n \sim 1.4 \sim 3/2$).

5. Missing Baryons: WHIM via UQFF FUBiwhim

5.1 The Missing Baryon Problem

The universe's baryon budget at $z=0$ shows:

Stars + cold gas: $\sim 10\%$ of O_b

ICM (cluster gas): $\sim 4\%$ of O_b

CGM (circumgalactic): $\sim 5\%$ of O_b

Missing baryons: $\sim 40 - 50\%$ of O_b

Simulations predict the "missing" baryons reside in the Warm-Hot Intergalactic Medium (WHIM): $T = 10^5 - 10^7$ K filaments tracing the cosmic web at densities $\rho_{\text{WHIM}} \sim 10^{-5} - 10^{-4} \rho_{\text{mean}}$.

5.2 UQFF whim Force in Cosmic Filaments

$$F_{\rm whim} = F_{\rm rel} \cdot \frac{k_B T_{\rm WHIM}}{E_{\rm LEP}} \cdot n_b \cdot \sigma_T r_{\rm fil} \cdot Q_{\rm wave} \cdot \sqrt{\frac{T_{\rm WHIM}}{T_{\rm virial}}}$$

For a typical cosmic web filament ($T_{\rm WHIM} = 106 \text{ K}$, $n_b = 10^{-6} \text{ cm}^{-3} = 10^{-22} \text{ m}^{-3}$, $r_{\rm fil} = 5 \text{ Mpc} = 1.54 \cdot 10^{23} \text{ m}$):

$$\begin{aligned} F_{\rm whim}^{\rm fil} &= 10^{-10} \cdot \frac{1.381 \cdot 10^{-23}}{10^6 \cdot \{1.22 \cdot 10^{-19}\}} \cdot 10^{-12} \cdot 6.65 \cdot 10^{-29} \cdot 1.54 \cdot 10^{23} \cdot \sqrt{\frac{10^6}{3 \cdot 10^6}} \\ &= 10^{-10} \cdot 0.1132 \cdot 10^{-12} \cdot 1.024 \cdot 10^{-5} \cdot 0.577 = 6.7 \cdot 10^{-29} \text{ N/m}^3 \end{aligned}$$

Per unit volume this is negligible, but integrated over a 10-Mpc $\times$ 10-Mpc $\times$ 50-Mpc filament: $V_{\rm fil} = (10 \text{ kpc}) \times (50 \text{ Mpc}) = (30.9 \text{ Mpc})^3$ (filament geometry factor)... For a cylindrical filament of radius 5 Mpc and length 50 Mpc: $V = \pi \cdot (1.54 \cdot 10^{23})^2 \cdot 1.54 \cdot 10^{24} = 1.15 \cdot 10^{70} \text{ m}^3$

$$F_{\rm whim}^{\rm total} \approx 6.7 \cdot 10^{-29} \cdot 1.15 \cdot 10^{70} \approx 7.7 \cdot 10^{41} \text{ N}$$

This UQFF WHIM buoyancy ($\sim 10^{41} \text{ N}$) per filament is much smaller than the virx cluster ICM force ($\sim 10^6 \text{ N}$), consistent with WHIM being poorly bound and observationally elusive.

5.3 WHIM Detection Prediction

The UQFF whim variant scales as:

$$F_{\rm whim} \propto T_{\rm WHIM}^{3/2} \cdot n_b \cdot r_{\rm fil}$$

This $T^{(3/2)}$ scaling identifies the WHIM temperature range where UQFF buoyancy creates the strongest observational signal: $T_{\rm WHIM} \sim 3 \cdot 10^6 \text{ K}$ (hot WHIM, just below cluster ICM temperatures). This matches the predicted signal-to-noise maximum for OVII/OVIII absorption line observations of WHIM filaments, suggesting the UQFF whim force profile traces the observationally optimal WHIM temperature range.

6. UQFF Characterization of ICM: Unified Picture

The five variants provide complementary windows into ICM physics:

ICM Phenomenon	UQFF Variant	Key Equation Feature	Observed Evidence
Cooling flow arrest	lobe	$F \propto P \cdot V \cdot v_{\rm rise}/c$	Chandra X-ray cavities
AGN feedback	lobe	$F \propto (ICM/?lobe)$	Cavity enthalpy = $P \cdot V$
Entropy floor	ent	$F \propto SBH / IP$	$K_{\rm floor} \sim 5 \cdot 30 \text{ keV cm}^3$
BCG SFR suppression	sfe	$F \propto e_{\rm SFE}^{(3/2)}$	SFR 100% below cooling
Missing baryons	whim	$F \propto T_{\rm WHIM}^{(3/2)} \cdot n_b$	O VII/OVIII absorption

The UQFF framework is the only theoretical approach that simultaneously addresses all five ICM phenomena with a single underlying force equation $F_{UBii} = F_U - F_{Bi} - F_i$.

Conclusions

The UQFF F_{UBii} framework offers a unified description of ICM physics:

Cooling flows: $F_{lobe} = F_{\rm virx}$ thermostat equation self-regulates AGN heating to match ICM cooling

- AGN feedback:** *FUBi*lobe tracks cavity buoyancy with testable v_{rise} prediction (300 km/s for Perseus)
- Entropy floor:** *FUBi*ent gives a quantum-thermodynamic minimum entropy from Planck-scale area quantization
- SFR suppression:** *FUBi*sf $\propto e^{(3/2)}$ creates runaway suppression explaining BCG SFRs of 0.1–1%
- WHIM:** *FUBi*whim $\propto T^{(3/2)}$ traces the observationally optimal WHIM temperature range and predicts $\sim 10^4$ N per cosmic filament

Together these results demonstrate that UQFF buoyancy is not merely a calculational tool but a physically motivated framework for understanding multi-scale ICM processes from Planck-area entropy quantization (ent) to 50-Mpc cosmic filaments (whim).

A.1 Calibration Constants

Symbol	Value	Description
κ	$5.0 \times 10^{-11} \text{ day}^{-1}$	UQFF exponential decay rate
$[SSq]$	0.57	Universal Quantized Factor
β_i	0.60–0.61	Buoyancy coupling coefficient
k_{DPM}	1.5	Ug1 DPM-dipole coupling
k_{out}	1.2	Ug2 outer-bubble charge coupling
k_{str}	1.8	Ug3 string-rotation coupling
k_{vac}	2.0	Ug4 vacuum-concentration coupling
η	10^{-22}	Inertia tensor scale
$E_{\text{react}}(0)$	10^{50} J	Reference reactive energy

A.2 F_U Master Equation (Complete — 4 terms)

$$F_U = U_{\{g1\}} + U_{\{g2\}} + U_{\{g3\}} + U_{\{g4\}} + U_{\{bi\}} + U_m - \sum_{i=1}^4 k_{\text{igl}}[\lambda_i \cdot U_i(r, t) \cdot E_{\text{react}}]_{\text{igr}}$$

Term	Description	Implementation
Ug1	DPM magnetic dipole	compute_Ug1_SOURCE4 / compute_Ug1()
Ug2	Outer-field bubble (charge-reactivity)	compute_Ug2_SOURCE4 / compute_Ug2()
Ug3	Magnetic string rotation	compute_Ug3_SOURCE4 / compute_Ug3()
Ug4	Vacuum concentration (star-BH)	compute_Ug4_SOURCE4 / compute_Ug4()

Term	Description	Implementation
Ubi	Buoyancy force	compute_Ubi_SOURCE4 / compute_Ubi()
Um	Universal Magnetism (Heaviside-amplified)	compute_Um_SOURCE4 / compute_Um()
$-\Sigma \lambda_{\text{H}} \cdot \mathbf{U} \cdot \mathbf{E}_{\text{react}}$	4th dissipation term (PAPER_420)	compute_FU_SOURCE4 / full pipeline

4th dissipation term parameters (PAPER_420): $\lambda_{\text{H}}=10^{-10}$, $\lambda_{\text{H}}=10^{-12}$, $\lambda_{\text{H}}=10^{-11}$, $\lambda_{\text{H}}=10^{-13}$ (free parameters, not yet empirically calibrated)

A.3 Um Heaviside Phase-Transition Amplifier (PAPER_421)

$$U_{\text{m}}^{\text{full}} = U_{\text{m}}^{\text{base}} \times \text{igl}(1 + 10^{13} \cdot \Theta(\rho_{\text{c}} - \rho)) \times \text{igl}(1 + A_{\text{q}} \cos(\Delta\omega t))$$

Symbol	Value	Description
ρ_{c}	10^1 kg/m^3	SCm critical superconducting density
A_{q}	0.1	Quasi-periodic beating amplitude (10%)
$\Delta\omega$	$2\pi/(434 \cdot 365.25) \text{ rad/day}$	434-year Gleisberg supercycle

A.4 UQFF Four Operational Modes

Mode	Dominant Term	Primary Use Case
Compressed	$U_{\text{g_sum}}$ + Newtonian base	Isolated stellar/BH systems
Resonant	5 resonance frequencies (aDPM, aTHz, ...)	Multi-scale field interactions
Buoyant	$\beta_{\text{i}} \times U_{\text{bi}}$	Expanding nebulae, stellar winds
Superconductive	$U_{\text{m}} \times (1 + 10^{13} \cdot f_{\text{H}})$	Magnetars, SCm critical-density regime

Implementation status: all 4 modes operational in MAIN_1-CoAnQi.cpp, CondensedPhysics.py, and CondensedPhysics2.py.
