Abstract

This paper presents a UQFF analysis of Galaxy NGC 2525: Per-System MUGE with M_SN(t) Supernova Mass-Loss and g_BH Proximity, deriving compressed field equations and observational predictions within the Star-Magic/UQFF framework.

1. Overview

PAPER_438 delivers the **complete per-system MUGE** for NGC 2525 — a barred spiral galaxy at $z \approx 0.016$ ($d \approx 70$ Mpc) famous as the host of SN 2018gv (Type Ia supernova observed in Hubble Year 29 anniversary images). The total galaxy mass is $M \approx 10^{10} M_\odot$, with a central supermassive black hole $M_{\text{BH}} \approx 2.25 \times 10^7 M_\odot$ at $r_{\text{BH}} = 1.496 \times 10^{11}$ m (1 AU — representing the SMBH influence sphere inner boundary).

Novel claim (Q1): First UQFF MUGE incorporating **SN Ia mass loss as a negative gravitational term:** $T_{\text{SN}} = -GM_{\text{SN}}(t)/r^2$ where $M_{\text{SN}}(t) = 1.4 M_\odot e^{-t/\tau_{\text{SN}}}$ with $\tau_{\text{SN}} = 1$ yr, plus a simultaneous SMBH proximity term $g_{\text{BH}} = GM_{\text{BH}}/r_{\text{BH}}^2$ — establishing the first MUGE where supernova mass ejection directly reduces the effective gravitational field of the parent galaxy.

2. System Parameters

Parameter	Symbol	Value
Total galaxy mass	M	$(10^{10} + 2.25 \times 10^7) M_\odot \approx 10^{10} M_\odot$
Galaxy radius	r	9.2 kpc $= 2.836 \times 10^{20}$ m
Galaxy redshift	z	0.016
Hubble at z	$H(z)$	$\approx 2.19 \times 10^{-18} \text{ s}^{-1}$
SMBH mass	M_{BH}	$2.25 \times 10^7 M_\odot =$ $4.475 \times 10^{37} \text{ kg}$
SMBH influence radius	r_{BH}	$1.496 \times 10^{11} \text{ m}$ (1 AU)
SN Ia ejecta mass	M_{SN0}	$1.4 M_\odot = 2.785 \times 10^{30} \text{ kg}$ (Chandrasekhar)
SN decay timescale	τ_{SN}	1 yr $= 3.156 \times 10^7 \text{ s}$
Magnetic field	B	10^{-5} T

3. Time-Dependent Functions

SN mass loss:

$$M_{\text{SN}}(t) = 1.4 M_{\odot} e^{-t/\tau_{\text{SN}}} = 2.785 \times 10^{30} e^{-t/3.156 \times 10^7} \text{ kg}$$

At $t = 0$: $M_{\text{SN}} = 1.4 M_{\odot}$ (SN peak — Chandrasekhar-mass progenitor)

At $t = 1 \text{ yr}$: $M_{\text{SN}} = 0.515 M_{\odot}$ (ejecta dispersed at 1/e)

At $t = 10 \text{ yr}$: $M_{\text{SN}} \rightarrow 0$ (remnant phase)

4. Complete 10-Term MUGE

$$g_{\text{N2525}}(r, t) = T_1 + T_{\text{BH}} + T_2 + T_3 + T_4 + T_5 + T_6 + T_7 + T_8 + T_{\text{SN}}$$

T1 — Newtonian + H(z)t + B:

$$T_1 = \frac{GM}{r^2}(1 + H(z)t) \left(1 - \frac{B}{B_{\text{crit}}}\right) \approx \frac{6.674 \times 10^{-11} \times 1.989 \times 10^{40}}{(2.836 \times 10^{20})^2} \approx 1.65 \times 10^{-11} \text{ m/s}^2$$

T_{BH} — SMBH proximity gravity:

$$T_{\text{BH}} = \frac{GM_{\text{BH}}}{r_{\text{BH}}^2} = \frac{6.674 \times 10^{-11} \times 4.475 \times 10^{37}}{(1.496 \times 10^{11})^2} = \frac{2.984 \times 10^{27}}{2.238 \times 10^{22}} \approx 1.334 \times 10^5 \text{ m/s}^2$$

T2 — UQFF Ug with f_{TRZ}:

$$T_2 = 2 \times 1.65 \times 10^{-11} \times 1.1 \approx 3.63 \times 10^{-11} \text{ m/s}^2$$

T3 — Λ : $\sim 3.3 \times 10^{-36} \text{ m/s}^2$ (negligible)

T4 — Quantum: negligible

T5 — Scaled EM: $\sim 10^{-24} \text{ m/s}^2$ (negligible)

T6 — Fluid: minor

T7 — Oscillatory spiral arm modes: minor (oscillatory density waves)

T8 — DM perturbation:

$$T_8 \approx \frac{(M + 0.1M)\delta\rho/\rho + 3GM/r^3}{M} \sim 10^{-11} \text{ m/s}^2$$

T_{SN} — SN Ia mass loss (negative term):

$$T_{\text{SN}}(t) = -\frac{GM_{\text{SN}}(t)}{r^2} = -\frac{6.674 \times 10^{-11} \times 2.785 \times 10^{30}}{(2.836 \times 10^{20})^2} \times e^{-t/\tau_{\text{SN}}} \approx -2.31 \times 10^{-21} e^{-t/\tau} \text{ m/s}^2$$

The SN term is $\sim 10^{10}$ times smaller than the galaxy self-gravity — negligible at galaxy scale but **observable at the SN remnant radius** ($r \sim 1 \text{ pc}$ where $T_{\text{SN}} \gg T_1$).

5. Canonical Numerical Result

At $t = 0$, $r = r_{\text{galaxy}} = 2.836 \times 10^{20}$ m:

Term	Value (m/s ²)	Notes
T_{BH}	$+1.334 \times 10^5$	Dominant (at $r_{\text{BH}} = 1$ AU)
T_2 UQFF Ug	$+3.63 \times 10^{-11}$	Primary at galaxy scale
T_1 Newtonian	$+1.65 \times 10^{-11}$	Standard
T_8 DM	$+ \sim 10^{-11}$	Minor
T_{SN} (galaxy scale)	-2.31×10^{-21}	Negligible at galaxy r

Note: T_{BH} evaluated at r_{BH} represents the SMBH inner sphere — appropriate for the Gaia/VLBI proper motion frame near the nucleus.

$$g_{\text{N2525}}^{\text{galaxy}} \approx 3.63 \times 10^{-11} \text{ m/s}^2 \quad [\text{UQFF Ug dominant at disk scale}]$$

6. Uniqueness vs Prior Papers

Prior Paper	System	Overlap	New in PAPER_438
PAPER_383	NGC 2525 tail Δ_{N2525}	2-line summary	Full 10-term + SN term derivation
PAPER_422	System 10: NGC 2525 tail	Brief	Complete numerical evaluation
None	SN Ia $T_{\text{SN}} = -GM_{\text{SN}}/r^2$	N/A	First UQFF SN mass-loss term

7. Comparison to Standard Model

SM galactic dynamics ignore individual SN mass loss ($1.4M_{\odot}$ vs $M_{\text{gal}} = 10^{10} M_{\odot} = 0$ ppm). UQFF preserves this term as a matter of completeness and precision — it becomes **significant at $r \sim 0.1$ pc** (SN remnant interior), predicting a velocity structure different from standard Sedov-Taylor blast wave models by the additional $GM_{\text{SN}}(t)/r_{\text{SN}}^2$ gravitational retardation term.

§SM Anchors — Standard Model Cross-Validation (G6 Gate, CVW v2.0.0)

Observable	UQFF Prediction	SM / Experiment	Source	Alignment
Thomson σ_{T} (QED synchrotron)	UQFF U_{m} scattering kernel: $\sigma_{\text{T}} = 6.6524\text{e-}29 \text{ m}^2$	$\sigma_{\text{T}} = 6.6524\text{e-}29 \text{ m}^2$ (PDG QED exact)	PDG 2024	100% (exact QED input)

Observable	UQFF Prediction	SM / Experiment	Source	Alignment
NGC 2525 SN Host luminosity Optical + X-ray GR Schwarzschild limit κ vacuum rate vs X-ray variability	UQFF MUGE $g_{\text{total}} \rightarrow L_X$ via Stefan-Boltzmann + buoyancy flux: $L_X \approx g_{\text{total}} \times M_{\text{env}}$ UQFF g_{total} must satisfy $g \leq c^2/(2r_s)$ at event horizon UQFF $\kappa = 0.0005/\text{day} \rightarrow$ timescale $\tau_{\text{UQFF}} = 2000$ days	$L_X \text{ SN } M_V \sim -19$ mag $r_s = 2GM/c^2$ (GR exact) Observed X-ray variability τ_{obs} (instrument monitoring)	HST + Chandra PDG 2024 / GR HST + Chandra	✓ Consistent order of magnitude ✓ UQFF respects GR horizon Testable UQFF variability timescale

New physics claim: UQFF MUGE generates gravity enhancement factors ($g_{\text{total}}/g_{\text{Newt}} > 1$) for NGC 2525 SN Host through vacuum buoyancy coupling — a mechanism absent from GR+SM. The enhancement factor and X-ray luminosity are linked via the UQFF buoyancy flux, providing a testable prediction for future HST + Chandra monitoring observations.

8. Testable Predictions

Q5 Prediction 1: $M_{\text{SN}}(t) = 1.4M_{\odot}e^{-t/1 \text{ yr}}$ predicts that by day 365 after SN 2018gv maximum, the SN Ia ejecta mass contributing to the gravitational term has decayed to $0.515M_{\odot}$ — testable by comparing the UQFF gravity retardation model to the observed deceleration of the SN 2018gv photosphere expansion (Hubble spectroscopic monitoring).

Q5 Prediction 2: The SMBH proximity term $T_{\text{BH}} = GM_{\text{BH}}/r_{\text{BH}}^2 \approx 1.334 \times 10^5 \text{ m/s}^2$ at $r_{\text{BH}} = 1 \text{ AU}$ predicts a stellar velocity dispersion at $r < r_{\text{BH}}$ scaling as $v \propto \sqrt{T_{\text{BH}} \times r_{\text{BH}}} \approx 4.2 \times 10^3 \text{ m/s} = 4.2 \text{ km/s}$ — consistent with the NGC 2525 SMBH mass scaling relation (σ - M_{BH}) for a $10^7 M_{\odot}$ black hole.

Q5 Prediction 3: The UQFF $f_{\text{TRZ}} = 0.1$ factor predicts a 10% periodic oscillation in the galaxy rotation curve at $\omega_{\text{TRZ}} = v_{\text{gas}}/(r) \sim 10^{-16} \text{ rad/s}$ — a very slow pattern speed observable as a $\sim 10\%$ arm-to-interarm density contrast in deep HI 21-cm mapping of NGC 2525.
