Abstract

This whitepaper catalogues 44 standalone sub-term physics calculator modules that constitute the atomic building blocks of the UQFF and MUGE frameworks. Each module encapsulates a single physical quantity — from aether vacuum densities and buoyancy coupling constants to solar cycle frequencies and stellar surface temperatures — as a self-contained C++ class. This catalogue provides a reference index for module equations, key parameter values, output ranges, and integration targets within MAIN_1_CoAnQi.cpp and CondensedPhysics.py.

1. Introduction

The 44 sub-term modules were extracted from grok_share_b0a3dc1d.txt (10,420 lines) and represent the granular physics underpinning the UQFF unified field equation:

$$F_{U,Bi,i} = \int [\text{Ug coupling} \cdot \text{vacuum terms} \cdot \text{buoyancy} \cdot \text{aether} \cdot \text{stellar params}] dx$$

Each module is implemented as a C++ class in modules/subterms/ with standard interface: computeX(), updateVariable(), getEquationText(), printVariables().

3. Integration Targets

3.1 MAIN_1_CoAnQi.cpp

Sub-term modules are candidates for batch extraction as PhysicsTerm subclasses:

```
// Example: ScmVacuumDensityModule → ScmVacuumDensityTerm
class ScmVacuumDensityTerm : public PhysicsTerm {
public:
    double compute(const SystemParams& params) override {
        return 7.09e-37; //  $\rho_{vac\_SCm}$  [J/m3]
    }
    std::string getName() const override { return "SCm Vacuum Density"; }
};
```

Target integration point: **Batch 24** in SOURCE1-116 registry near line 6688+.

3.2 CondensedPhysics.py

Each sub-term module maps to a Calculator class method:

```
class SubTermCalculator:
    def compute_aether_vacuum_density(self) -> dict:
        # Returns  $\rho_{vac\_A} = 7.09e-36$  J/m3 with equation text
```

Target: new UQFFSubTermCalculator in CondensedPhysics.py Part 5 (after line 60000).

3.3 index.js

Module constants exportable as:

```
const SUB_TERMS = {
    rho_vac_UA: 7.09e-36, // J/m3
    rho_vac_SCm: 7.09e-37, // J/m3
    beta_i: 0.6, // buoyancy coupling
    kappa: 0.0005/86400, // per-second DPM rate
    SSq: 0.57, // SCm calibration
};
```

5. Scientific Context

The 44 sub-term modules collectively represent a field-theoretic decomposition of gravity that accounts for:

- **Vacuum energy hierarchy:** $\rho_{UA} : \rho_{SCm} : \rho_{cosm} = 10 : 1 : 0.001$
- **Coupling hierarchy:** k_3 (string/rotation) $> k_1$ (dipole) $> k_2$ (charge) $> k_4$ (vacuum)
- **Time evolution:** DPM birth model $\rightarrow$ inflation $\rightarrow$ SCm decay $\rightarrow$ solar wind modulation $\rightarrow$ present
- **Multi-scale validity:** Sub-parsec (heliosphere) to Gpc (galaxy clusters)

6. Conclusion

This catalogue documents 44 atomic physics calculator modules that implement the sub-term physics of the UQFF/MUGE framework. The modules span vacuum energy, coupling constants, stellar parameters, galactic scales, and quantum field calculators. They constitute the modules/subterms/ library and are ready for integration as PhysicsTerm subclasses in MAIN_1_CoAnQi.cpp or as Python calculator methods in CondensedPhysics.py.

GR Schwarzschild limit	UQFF g_total must satisfy $g \leq c^2/(2r_s)$ at event horizon	$r_s = 2GM/c^2$ (GR exact)	PDG 2024 / GR	✓ UQFF respects GR horizon

Observable	UQFF Prediction	SM / Experiment	Source	Alignment
κ vacuum rate vs X-ray variability	UQFF $\kappa =$ 0.0005/day $\rightarrow$ timescale $\tau_{\text{UQFF}} =$ 2000 days	Observed X-ray variability τ_{obs} (instrument monitoring)	Chandra CXC	Testable UQFF variability timescale

New physics claim: UQFF MUGE generates gravity enhancement factors ($g_{\text{total}}/g_{\text{Newt}} > 1$) for Astrophysical system through vacuum buoyancy coupling — a mechanism absent from GR+SM. The enhancement factor and X-ray luminosity are linked via the UQFF buoyancy flux, providing a testable prediction for future Chandra CXC monitoring observations.
